Preface

Thank you very much for making use of Toshiba microcomputer LSIs.
Before use this LSI, refer the section, “Notes and Restrictions”.

CMOS 32-Bit Microcontrollers

TMP92CY23FG/TMP92CY23DFG/TMP92CD23AFG/TMP92CD23ADFG

1. Outline and Device Characteristics

The TMP92CY23/CD23A are a high-speed advanced 32-bit Microcontroller developed for controlling equipment which processes mass data.

The TMP92CY23/CD23A has a high-performance CPU (900/H1 CPU) and various built-in I/Os.

TMP92CY23FG, TMP92CY23FG, TMP92CD23AFG and TMP92CD23ADFG are housed in a 100-pin flat package.

Product Name	RAM	ROM	Package
TMP92CY23FG TMP92CY23DFG	16K byte	256K byte	LQFP100-P-1414-0.50F QFP-P-1420-0.65A
TMP92CD23AFG TMP92CD23ADFG	32K byte	512K byte	LQFP100-P-1414-0.50F QFP-P-1420-0.65A

Device characteristics are as follows:

(1) CPU: 32-bit CPU (900/H1 CPU)
- Compatible with 900/L1 instruction code
- 16 Mbytes of linear address space
- General-purpose register and register banks
- Micro DMA: 8 channels (250 ns/4 bytes at f_{SYS} = 20 MHz, best case)

(2) Minimum instruction execution time: 50 ns (at f_{SYS} = 20 MHz)

(3) External memory expansion
- Expandable up to 16 Mbytes (Shared program/data area)
- Can simultaneously support 8- or 16-bit width external data bus
  ···Dynamic data bus sizing
- Separate bus system

(4) Memory controller
- Chip select output: 4 channels

(5) 8-bit timers: 6 channels

(6) 16-bit timers: 2 channels

(7) General-purpose serial interface: 3 channels
- UART/synchronous mode: 3 channels (channel 0 , 1 and 2)
- IrDA ver.1.0 (115 kbps) mode selectable: 3 channels (channel 0 , 1 and 2)

(8) Serial bus interface: 2 channels
- I^2C bus mode
- Clock synchronous mode

(9) High Speed serial interface: 1 channels

Note: This circuit is not built into TMP92CY23.

(10) 10-bit AD converter: 12 channels

(11) Watchdog timer

(12) Special timer for CLOCK

(13) Key-on wake up (only for HALT release):8 channels

(14) Program patch logic: 8 banks

(15) Interrupts: TMP92CY23: 50 interrupts, TMP92CD23A: 51 interrupts

- 9 CPU interrupts: Software interrupt instruction and illegal instruction
- 32 internal interrupts (TMP92CY23), 33 internal interrupts (TMP92CD23A)
  : Seven selectable priority levels
- 9 external interrupts (INT0 to INT7 and $\overline{NMI}$): Seven selectable priority levels
  (INT0 to INT7 selectable edge or level interrupt)

(16) Input/output ports: 84 pins

(17) Standby function

- Three HALT modes: IDLE2 (Programmable), IDLE1, STOP

(18) Clock controller

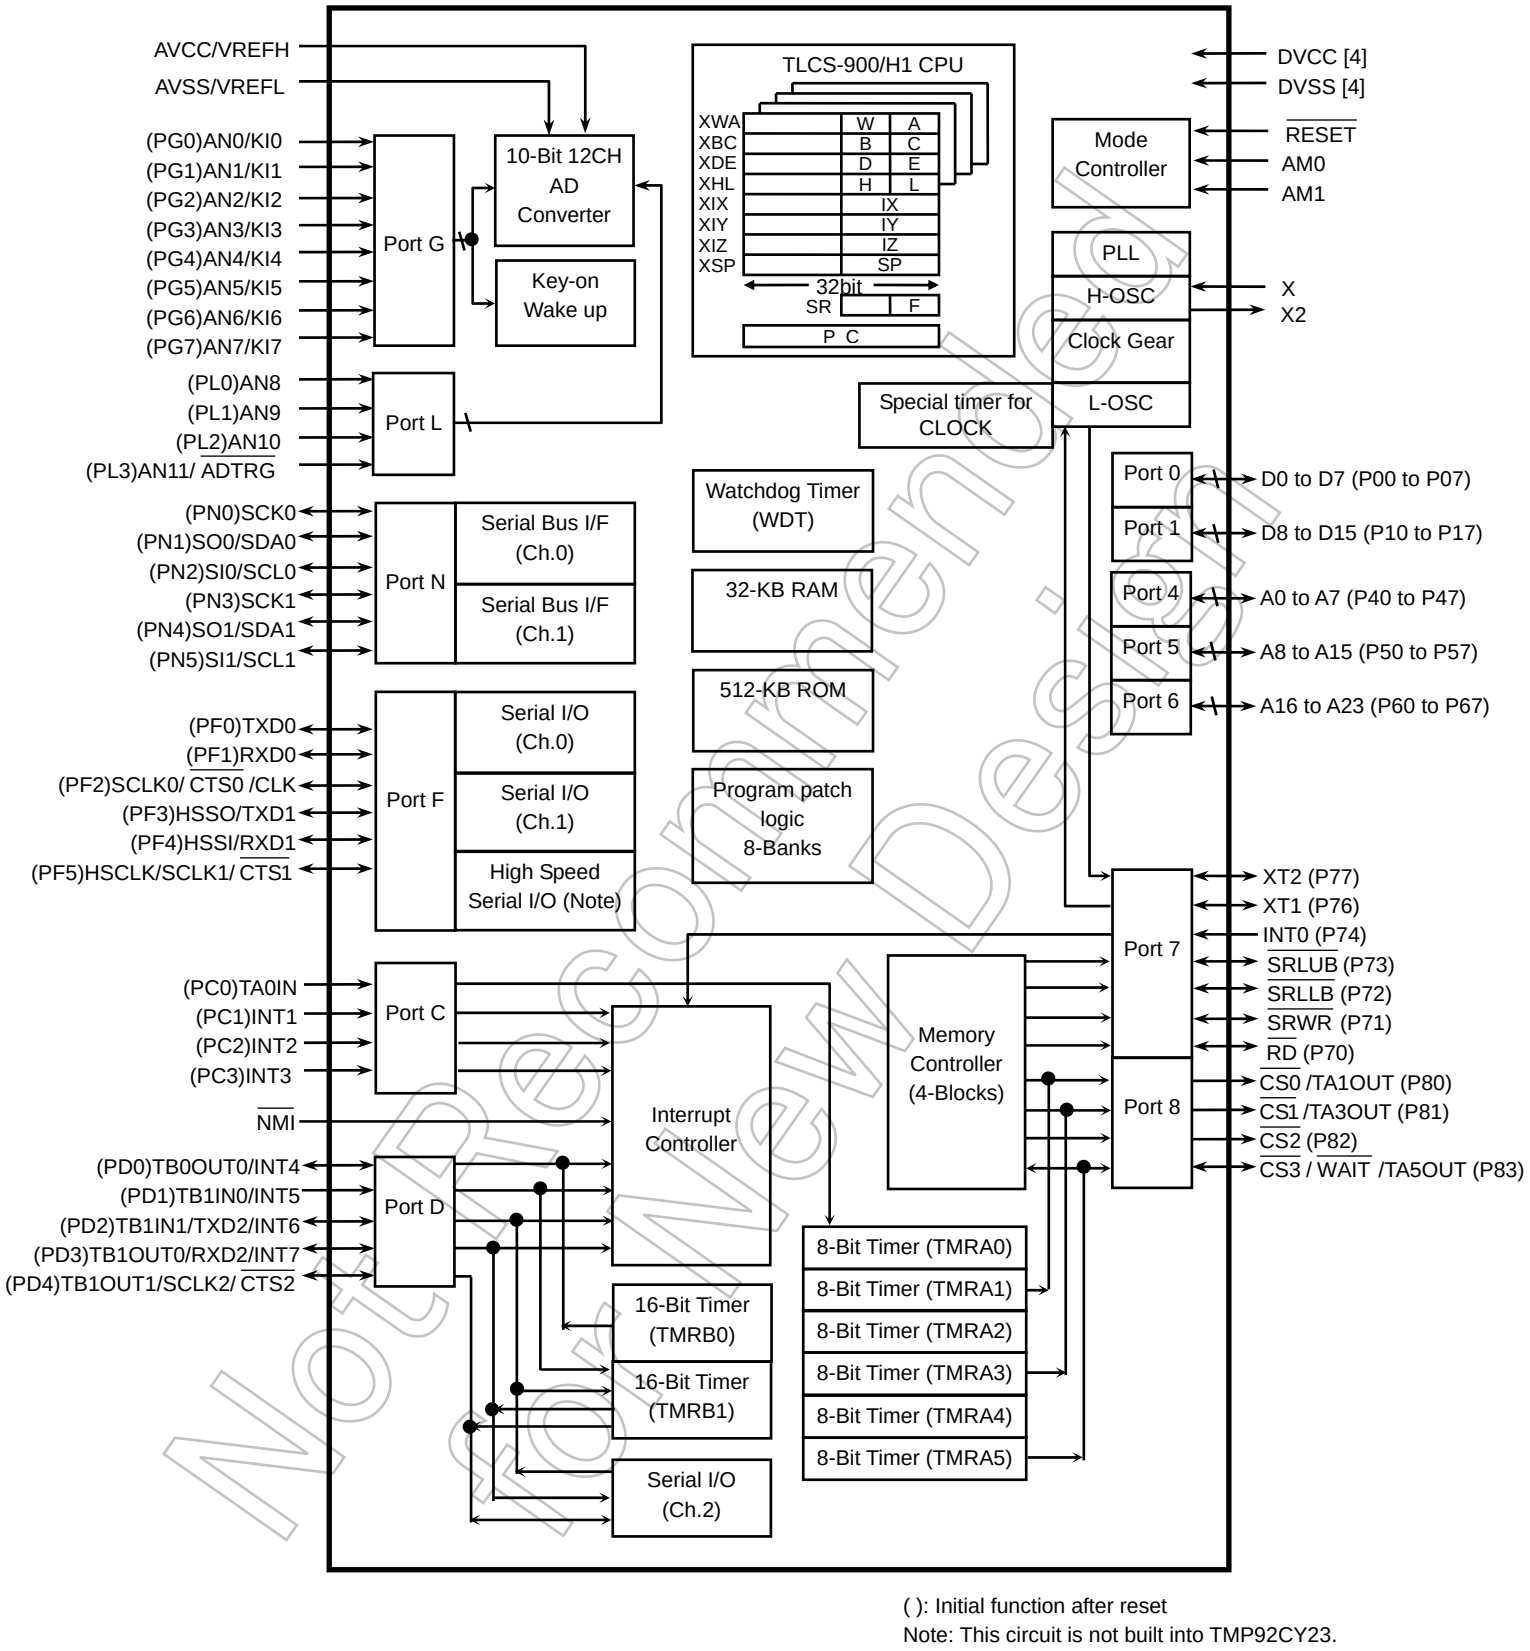
- Clock doubler (PLL)
- Clock gear function: Select high-frequency clock fc to fc/16
- Special timer for CLOCK (fs = 32.768 kHz)

(19) Operating voltage

- V_{CC} = 3.0 V to 3.6 V (fc max = 40 MHz、f_{OSCH} max = 10MHz(TMP92CD23A))

(20) Package

- 100-pin QFP: LQFP100-P-1414-0.50F (TMP92CY23FG/TMP92CD23AFG)
  QFP100-P-1420-0.65A (TMP92CY23DFG/TMP92CD23ADFG)



( ): Initial function after reset
Note: This circuit is not built into TMP92CY23.

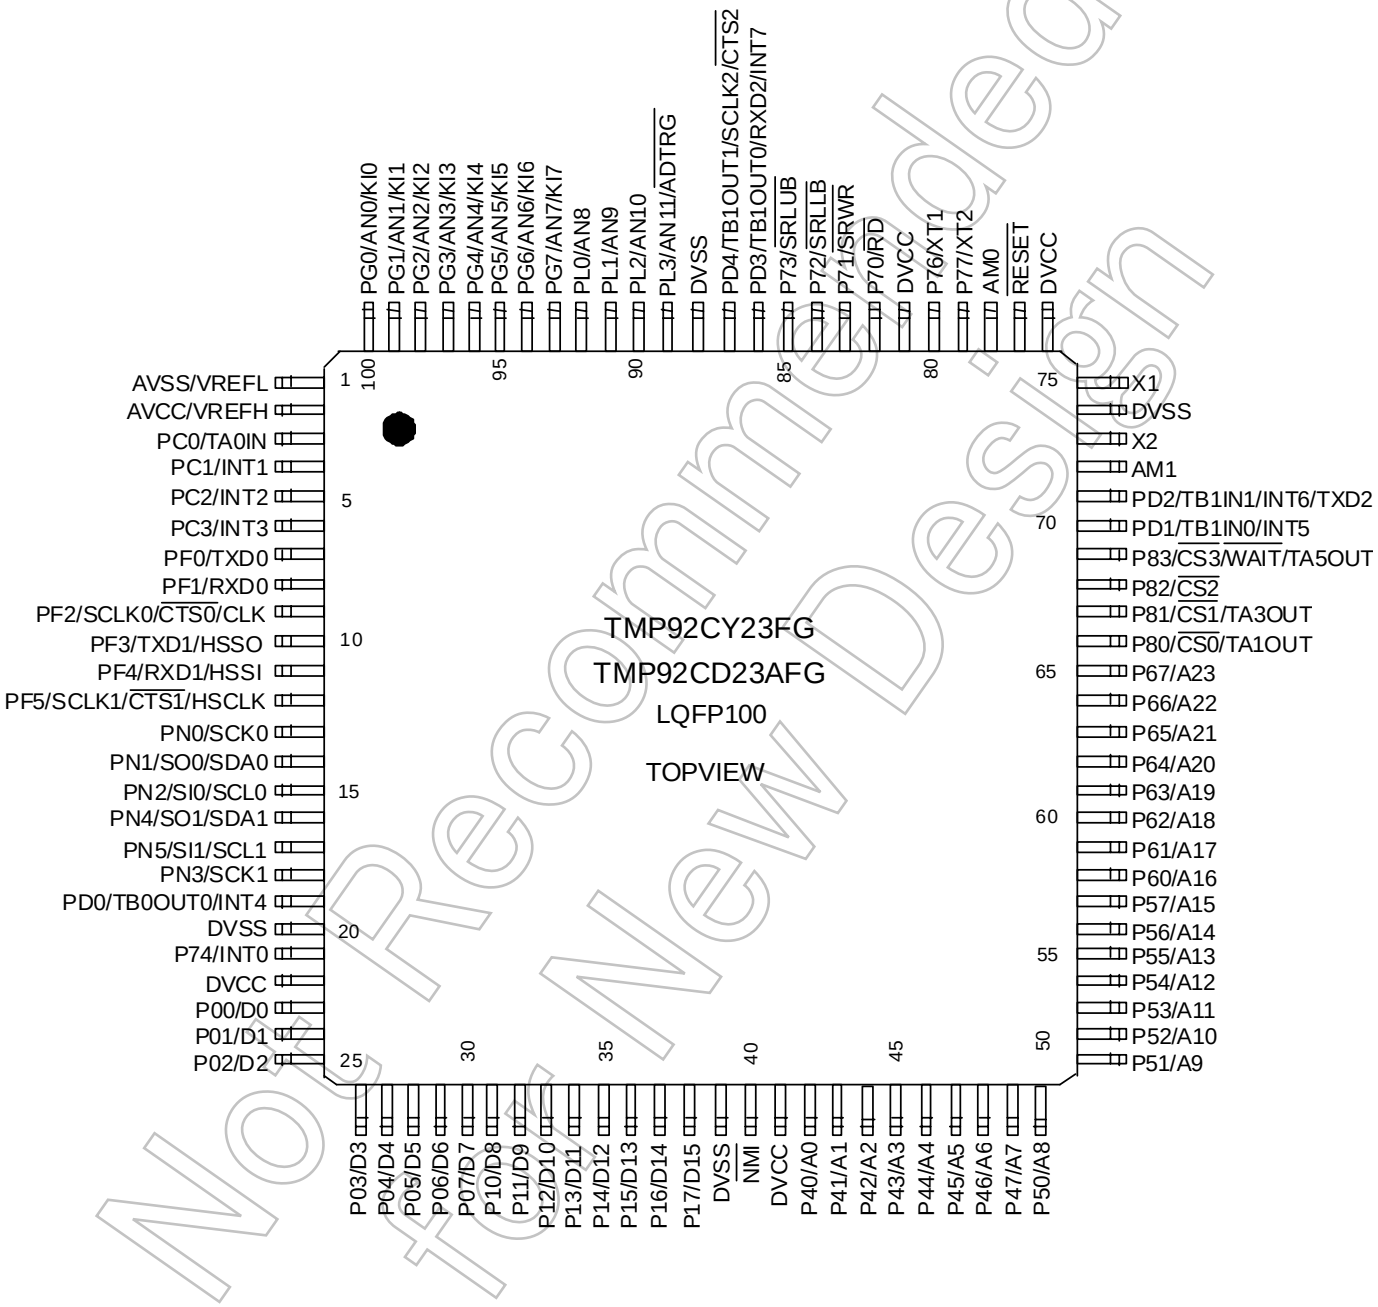
Figure 1.1 TMP92CY23/CD23A Block Diagram

2. Pin Assignment and Functions

The assignment of input/output pins for the TMP92CY23/CD23A, their names and functions are as follows:

2.1 Pin Assignment Diagram

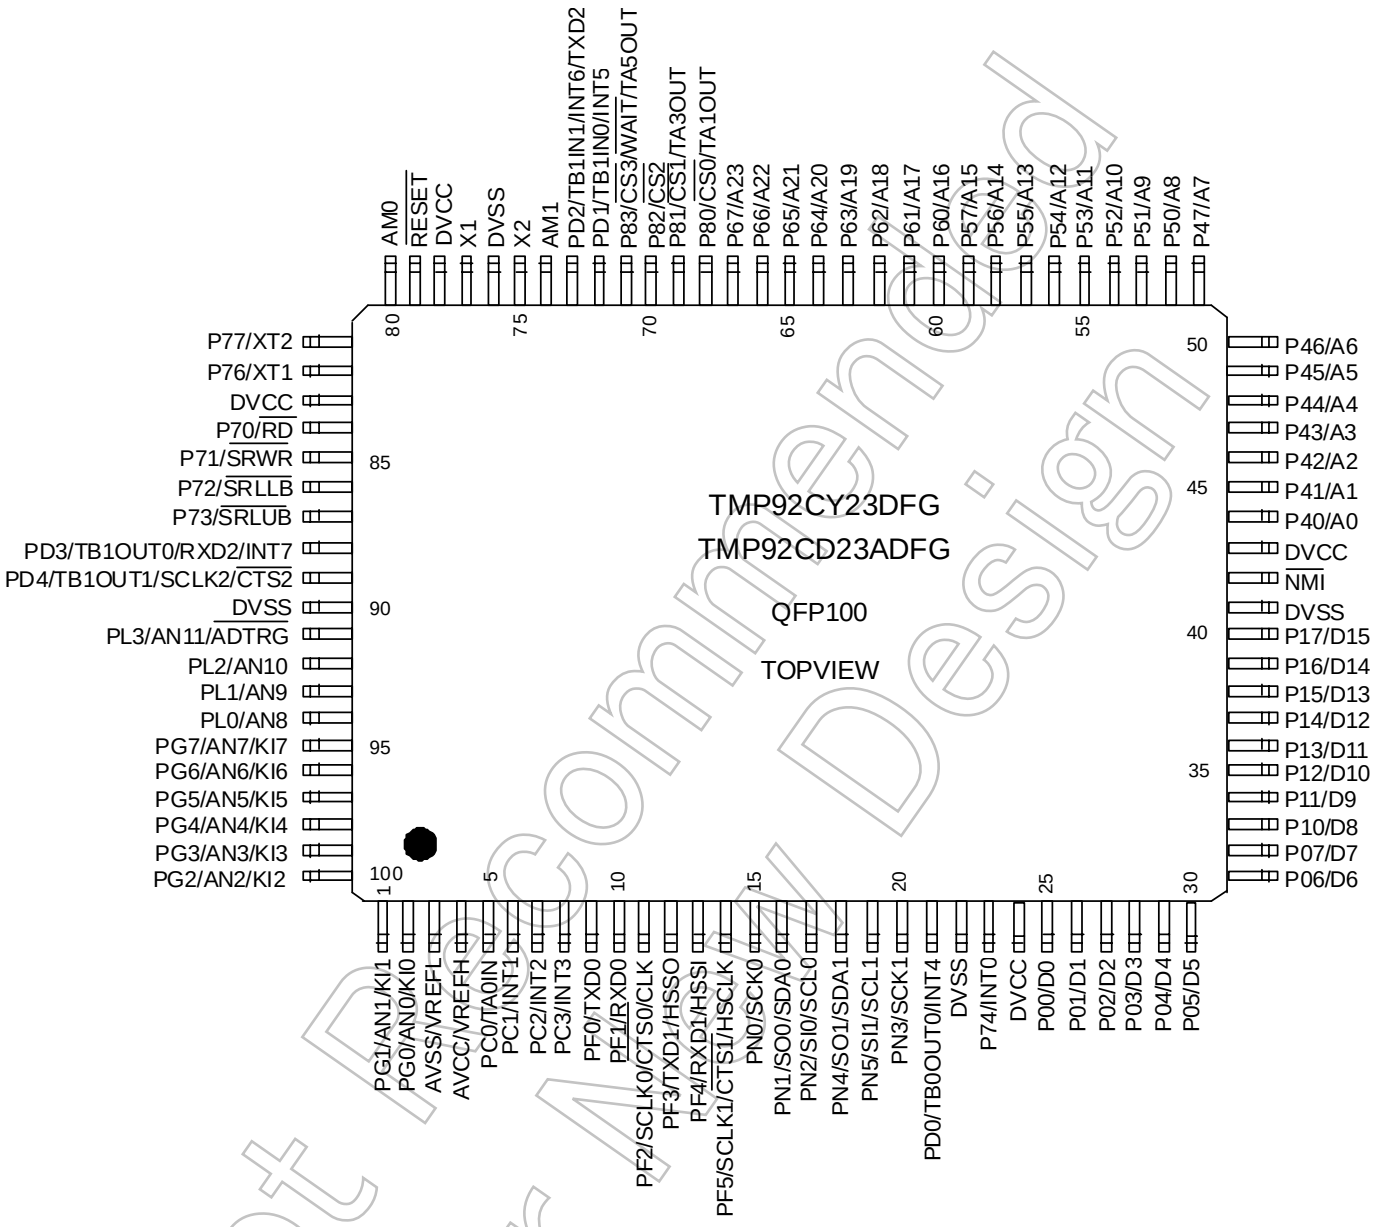
Figure 2.1.1 shows the pin assignment of the TMP92CY23FG/TMP92CD23AFG.



Note: HSSO, HSSI and HSCLK functions are not built into TMP92CY23.

Figure 2.1.1 Pin Assignment Diagram (100-pin LQFP)

Figure 2.1.2 shows the pin assignment of the TMP92CY23DFG/TMP92CD23ADFG.



Note: HSSO, HSSI and HSCLK functions are not built into TMP92CY23.

Figure 2.1.2 Pin Assignment Diagram (100-pin QFP)

2.2 Pin Names and Functions

The following table shows the names and functions of the input/output pins.

Table 2.2.1 Pin Names and Functions (1/3)

Pin name	Number of Pin	I/O	Function
P00 to P07	8	I/O	Port 0: I/O port Input or output specifiable in units of bits
D0 to D7		I/O	Data: Data bus 0 to 7
P10 to P17	8	I/O	Port 1: I/O port Input or output specifiable in units of bits
D8 to D15		I/O	Data: Data bus 8 to 15
P40 to P47	8	I/O	Port 4: I/O port Input or output specifiable in units of bits
A0 to A7		Output	Address: Address bus 0 to 7
P50 to P57	8	I/O	Port 5: I/O port Input or output specifiable in units of bits
A8 to A15		Output	Address: Address bus 8 to 15
P60 to P67	8	I/O	Port 6: I/O port Input or output specifiable in units of bits
A16 to A23		Output	Address: Address bus 16 to 23
P70	1	I/O	Port 70: I/O port (Schmitt input, with pull-up resistor)
$\overline{RD}$		Output	Read: Outputs strobe signal for read external memory.
P71	1	I/O	Port 71: I/O port (Schmitt input, with pull-up resistor)
$\overline{SRWR}$		Output	Write enable for SRAM: Strobe signal for wiritng data.
P72	1	I/O	Port 72: I/O port (Schmitt input, with pull-up resistor)
$\overline{SRLLB}$		Output	Data enable for SRAM on pins D0 to D7
P73	1	I/O	Port 73: I/O port (Schmitt input, with pull-up resistor)
$\overline{SRLUB}$		Output	Data enable for SRAM on pins D8 to D15
P74	1	Input	Port 74: Input port (Schmitt input)
INT0		Input	Interrupt request pin 0 : Interrupt request pin with programmable level/rising/falling edge
P76	1	I/O	Port 76: I/O port (Open drain output)
XT1		Input	Low-frequency oscillator connection Input pins
P77	1	I/O	Port 77: I/O port (Open drain output)
XT2		Output	Low-frequency oscillator connection Output pins
P80	1	Output	Port 80: Output port
$\overline{CS0}$		Output	Chip select 0: Outputs “Low” when address is within specified address area
TA1OUT		Output	8-bit timer 1 Output: Output pin of 8-bit timer TMRA0 or TMRA1
P81	1	Output	Port 81: Output port
$\overline{CS1}$		Output	Chip select 1: Outputs “Low” when address is within specified address area
TA3OUT		Output	8-bit timer 3 Output: Output pin of 8-bit timer TMRA2 or TMRA3
P82	1	Output	Port 82: Output port
$\overline{CS2}$		Output	Chip select 2: Outputs “Low” when address is within specified address area
P83	1	I/O	Port 83: I/O port (Schmitt input)
$\overline{CS3}$		Output	Chip select 3: Outputs “Low” when address is within specified address area
TA5OUT		Output	8-bit timer 5 Output: Output pin of 8-bit timer TMRA4 or TMRA5
$\overline{WAIT}$		Input	Wait: Signal used to request CPU bus wait
PC0	1	Input	Port C0: Input port (Schmitt input)
TA0IN		Input	8-bit timer 0 input: Input pin of 8-bit timer TMRA0
PC1	1	Input	Port C1: Input port (Schmitt input)
INT1		Input	Interrupt request pin 1 : Interrupt request pin with programmable level/rising/falling edge
PC2	1	Input	Port C2: Input port (Schmitt input)
INT2		Input	Interrupt request pin 2 : Interrupt request pin with programmable level/rising/falling edge
PC3	1	Input	Port C3: Input port (Schmitt input)
INT3		Input	Interrupt request pin 3 : Interrupt request pin with programmable level/rising/falling edge

Table 2.2.2 Pin Names and Functions (2/3)

Pin name	Number of Pin	I/O	Function
PD0	1	I/O	Port D0: I/O port (Schmitt input)
TB0OUT0		Output	16-bit timer 0 output 0: Output pin of 16-bit timer TMRB0
INT4		Input	Interrupt request pin 4 : Interrupt request pin with programmable level/rising/falling edge
PD1	1	Input	Port D1: Input port (Schmitt input)
TB1IN0		Input	16-bit timer 1 input 0: Input of count/capture trigger in 16-bit timer TMRB1
INT5		Input	Interrupt request pin 5 : Interrupt request pin with programmable level/rising/falling edge
PD2	1	I/O	Port D2: I/O port (Schmitt input)
TB1IN1		Input	16-bit timer 1 input 1: Input of count/capture trigger in 16-bit timer TMRB1
TXD2		Output	Serial 2 send data: Open drain output programmable
INT6		Input	Interrupt request pin 6 : Interrupt request pin with programmable level/rising/falling edge
PD3	1	I/O	Port D3: I/O port (Schmitt input)
TB1OUT0		Output	16-bit timer 1 output 0: Output pin of 16-bit timer TMRB1
RXD2		Input	Serial 2 receive data
INT7		Input	Interrupt request pin 7 : Interrupt request pin with programmable level/rising/falling edge
PD4	1	I/O	Port D4: I/O port (Schmitt input)
TB1OUT1		Output	16-bit timer 1 output 1: Output pin of 16-bit timer TMRB1
SCLK2		I/O	Serial 2 clock I/O
$\overline{\text{CTS2}}$		Input	Serial 2 data send enable (Clear to send)
PF0	1	I/O	Port F0: I/O port (Schmitt input)
TXD0		Output	Serial 0 send data: Open drain output programmable
PF1	1	I/O	Port F1: I/O port (Schmitt input)
RXD0		Input	Serial 0 receive data
PF2	1	I/O	Port F2: I/O port (Schmitt input)
SCLK0		I/O	Serial 0 clock I/O
$\overline{\text{CTS0}}$		Input	Serial 0 data send enable (Clear to send)
CLK		Output	Clock: System Clock output
PF3	1	I/O	Port F3: I/O port (Schmitt input)
TXD1		Output	Serial 1 send data: Open drain output programmable
HSSO		Output	High speed Serial send data (Note)
PF4	1	I/O	Port F4: I/O port (Schmitt input)
RXD1		Input	Serial 1 receive data
HSSI		Input	High speed Serial receive data (Note)
PF5	1	I/O	Port F5: I/O port (Schmitt input)
SCLK1		I/O	Serial 1 clock I/O
$\overline{\text{CTS1}}$		Input	Serial 1 data send enable (Clear to send)
HSCLK		Output	High speed Serial clock output (Note)
PG0 to PG7	8	Input	Port G: Input port (Schmitt input)
AN0 to AN7			Analog input 0 to 7: Pin used to input to AD conveter
KI0 to KI7			Key input 0 to 7: Pin used for key-on wakeup 0 to 7
PL0 to PL3	4	Input	Port L: Input port (Schmitt input)
AN8 to AN11			Analog input 8 to 11: Pin used for input to A/D conveter
$\overline{\text{ADTRG}}$			A/D trigger: Signal used for request A/D start (Shared with PL3)

Note: HSSO, HSSI and HSCLK functions are not built into TMP92CY23.

Table 2.2.3 Pin Names and Functions (3/3)

Pin name	Number of Pin	I/O	Function
PN0	1	I/O	Port N0: I/O port (Schmitt input)
SCK0		I/O	Serial bus interface 0 clock I/O data at SIO mode
PN1	1	I/O	Port N1: I/O port (Schmitt input, Open drain output)
SO0		Output	Serial bus interface 0 send data at SIO mode
SDA0		I/O	Serial bus interface 0 send/receive data at I^2C mode
PN2	1	I/O	Port N2: I/O port (Schmitt input, Open drain output)
SI0		Input	Serial bus interface 0 receive data at SIO mode
SCL0		I/O	Serial bus interface 0 clock I/O data at I^2C mode
PN3	1	I/O	Port N3: I/O port (Schmitt input)
SCK1		I/O	Serial bus interface 1 clock I/O data at SIO mode
PN4	1	I/O	Port N4: I/O port (Schmitt input, Open drain output)
SO1		Output	Serial bus interface 1 send data at SIO mode
SDA1		I/O	Serial bus interface 1 send/receive data at I^2C mode
PN5	1	I/O	Port N5: I/O port (Schmitt input, Open drain output)
SI1		Input	Serial bus interface 1 receive data at SIO mode
SCL1		I/O	Serial bus interface 1 clock I/O data at I^2C mode
$\overline{NMI}$	1	Input	Non-maskable interrupt request pin: Interrupt request pin with programmable falling edge level or with both edge levels programmable (Schmitt input)
AM0, AM1	2	Input	Operation mode: Fixed to AM1 = "1" and AM0 = "1"
X1 / X2	2	I/O	High-frequency oscillator connection I/O pins
$\overline{RESET}$	1	Input	Reset: Intializes TMP92CY23/CD23A (Schmitt input, with pull-up resistor)
AVCC / VREFH	1	Input	Pin used for both power supply pin for AD converter and standard power supply for AD converter (H)
AVSS / VREFL	1	Input	Pin used for both GND pin for AD converter (0 V) and standard power supply pin for AD converter (L)
DVCC	4	–	Power supply pins (All DVCC pins should be connected to the power supply pin)
DVSS	4	–	GND pins (0 V) (All DVSS pins shold be connected to GND(0V))

3. Operation

This section describes the basic components, functions and operation of the TMP92CY23/CD23A.

3.1 CPU

The TMP92CY23/CD23A contains an advanced high-speed 32-bit CPU (TLCS-900/H1 CPU)

3.1.1 CPU Outline

The TLCS-900/H1 CPU is a high-speed, high-performance CPU based on the TLCS-900/L1 CPU. The TLCS-900/H1 CPU has an expanded 32-bit internal data bus to process instructions more quickly.

The following is an outline of the CPU:

Table 3.1.1 TMP92CY23/CD23A Outline

Parameter	TMP92CY23/CD23A
Width of CPU address bus	24 bits
Width of CPU data bus	32 bits
Internal operating frequency	Max 20 MHz
Minimum bus cycle	1-clock access (50 ns at f_{SYS} = 20MHz)
Internal RAM	32-bit 1-clock access
Internal ROM	32-bit interleave 2-1-1-1-clock access
Internal I/O	8-bit 2-clock access
External SRAM, Masked ROM	8- or 16-bit 2-clock access (waits can be inserted)
Minimum instruction execution cycle	1-clock (50 ns at f_{SYS} =20MHz)
Conditional jump	2-clock (100 ns at f_{SYS} =20MHz)
Instruction queue buffer	12 bytes
Instruction set	Compatible with TLCS-900/L1 (LDX instruction is deleted)
CPU mode	Maximum mode only
Micro DMA	8 channels

3.1.2 Reset Operation

When resetting the TMP92CY23/CD23A, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the $\overline{\text{RESET}}$ input low for at least 20 system clocks (64 μs at fc = 10 MHz).

At reset, since the clock doubler (PLL) is bypassed and the clock-gear is set to 1/16, the system clock operates at 312.5 kHz (fc = 10 MHz).

When the reset has been accepted, the CPU performs the following:

- Sets the program counter (PC) as follows in accordance with the reset vector stored at address FFFF00H to FFFF02H:

  PC<7:0> ← data in location FFFF00H
  PC<15:8> ← data in location FFFF01H
  PC<23:16> ← data in location FFFF02H
- Sets the stack pointer (XSP) to 00000000H.
- Sets bits <IFF2:0> of the status register (SR) to 111 (thereby setting the interrupt level mask register to level 7).
- Clears bits <RFP1:0> of the status register to 00 (there by selecting register bank 0).

When the reset is released, the CPU starts executing instructions according to the program counter settings. CPU internal registers not mentioned above do not change when the reset is released.

When the reset is accepted, the CPU sets internal I/O, ports and other pins as follows.

- Initializes the internal I/O registers.
- Sets the port pins, including the pins that also act as internal I/O, to general-purpose input or output port mode.

A $\overline{\text{RESET}}$ input terminal becomes “High”, if reset release is carried out, a built-in FlashROM warm-up circuit (notes) will start operation, and internal reset will be canceled after the end of the circuit of operation.

Memory controller operation cannot be ensured until the power supply becomes stable after power-on reset. External RAM data provided before turning on the TMP92CY23/CD23A may be corrupted because the control signals are unstable until the power supply becomes stable after power-on reset.

Note: Although this product is a MaskROM product, in order to consider as the same operation as a FlashROM product, built-in FlashROM warm-up time enters. The warm-up time of build-in FlashROM into becomes it as follows.

at f_{OSCH} = 10 MHz
409.6μs (2^{12} / f_{OSCH})

Figure 3.1.1 shows the example of operating the reset timing of TMP92CY23/CD23A.

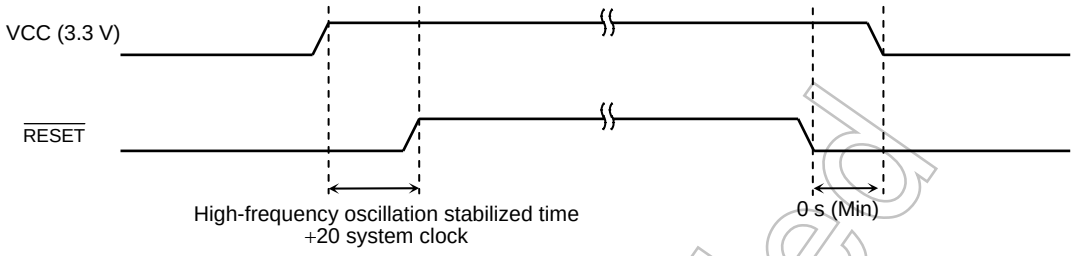


Figure 3.1.1 Power on Reset Timing Example

3.1.3 Setting of AM0 and AM1

Set AM1 and AM0 pins as shown in Table 3.1.2 according to system usage.

Table 3.1.2 Operation Mode Setup Table

Operation Mode	Mode Setup Input Pin		
	RESET	AM1	AM0
Internal ROM starting	↗	1	1

3.2 Memory Map

Figure 3.2.2 show the memory maps of the TMP92CY23, and Figure 3.2.2 show the memory maps of the TMP92CD23A respectively.

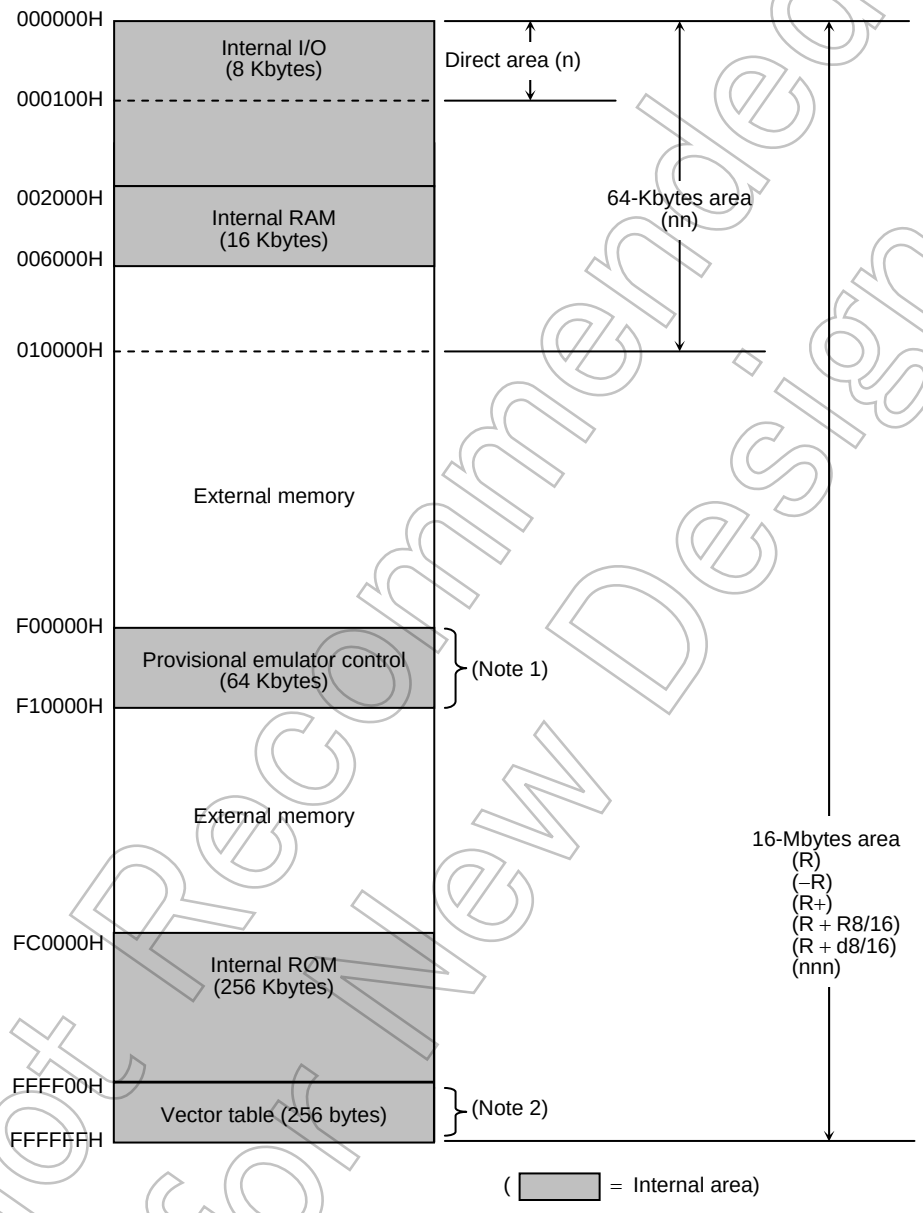

Figure 3.2.1 TMP92CY23 Memory map

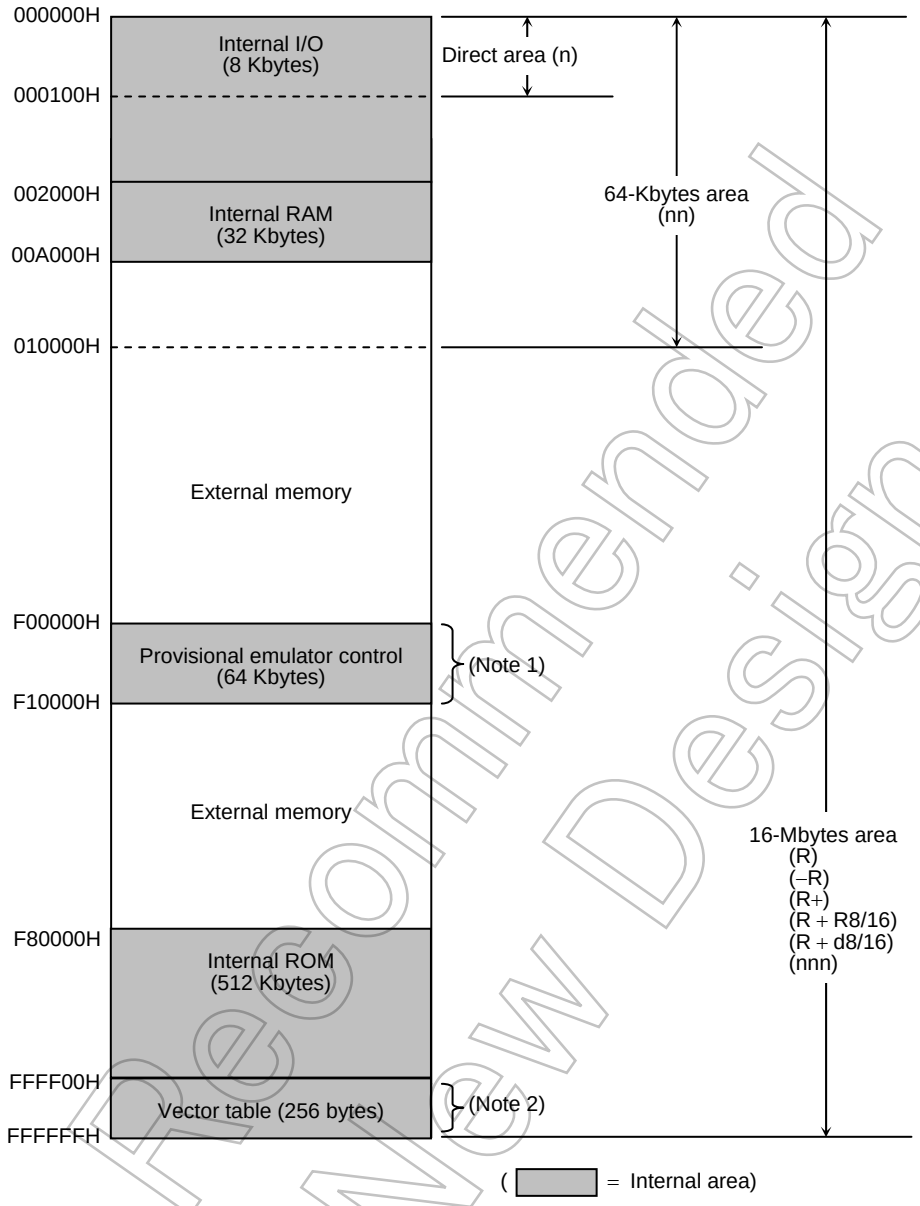

Figure 3.2.2 TMP92CD23A Memory Map

Note 1: The Provisional emulator control area, mapped F00000H to F0FFFFH after reset, is for emulator use and so is not available. When emulator $\overline{\text{SRWR}}$ signal and $\overline{\text{RD}}$ signal are asserted, this area is accessed. Ensure external memory is used.

Note 2: Do not use the last 16-byte area (FFFFF0H to FFFFFFH). This area is reserved for an emulator.

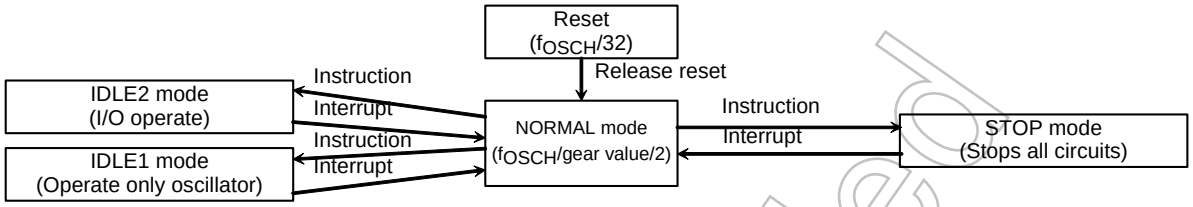
3.3 Clock Function and Stand-by Function

The TMP92CY23/CD23A contains (1) clock gear, (2) clock doubler (PLL), (3) stand-by controller and (4) noise reduction circuits. They are used for low power, low noise systems.

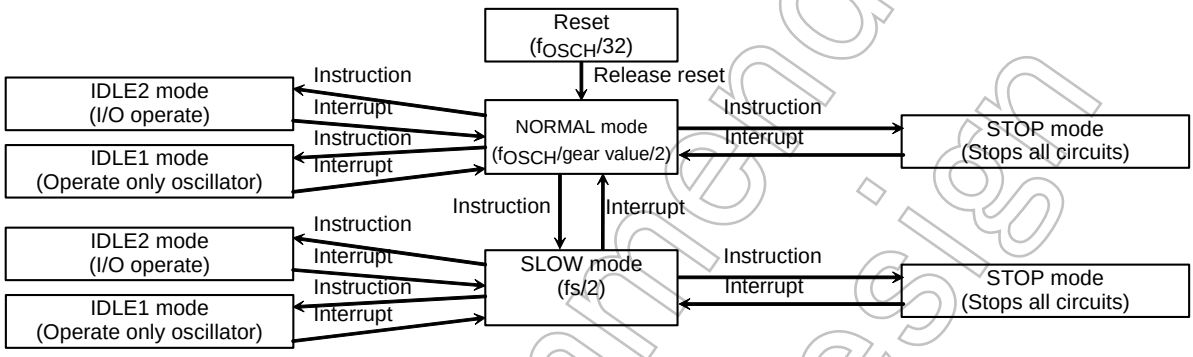
This chapter is organized as follows:

The clock operating modes are as follows: (a) single clock mode (X1, X2 pins only), (b) dual clock mode (X1, X2, XT1 and XT2 pins) and (c) triple clock mode (X1, X2, XT1 and XT2 pins and PLL).

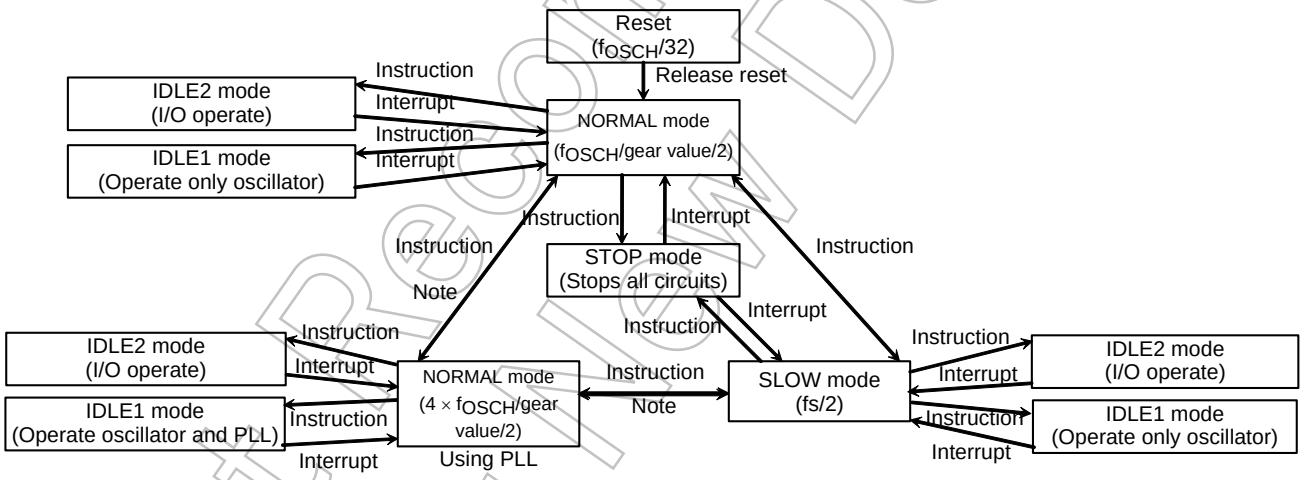
Figure 3.3.1 shows a transition figure.



(a) Single clock mode transition figure



(b) Dual clock mode transition figure



(c) Triple clock mode transition figure

Note 1: It is not possible to control PLL in SLOW mode when shifting from SLOW mode to NORMAL mode with use of PLL. (PLL start up/stop/change write to PLLCR0<PLLON>, PLLCR1<FCSEL> register)

Note 2: When shifting from NORMAL mode with use of PLL to NORMAL mode, execute the following setting in the same order.

1) Change CPU clock (PLLCR0<FCSEL> ← "0")

2) Stop PLL circuit (PLLCR1<PLLON> ← "0")

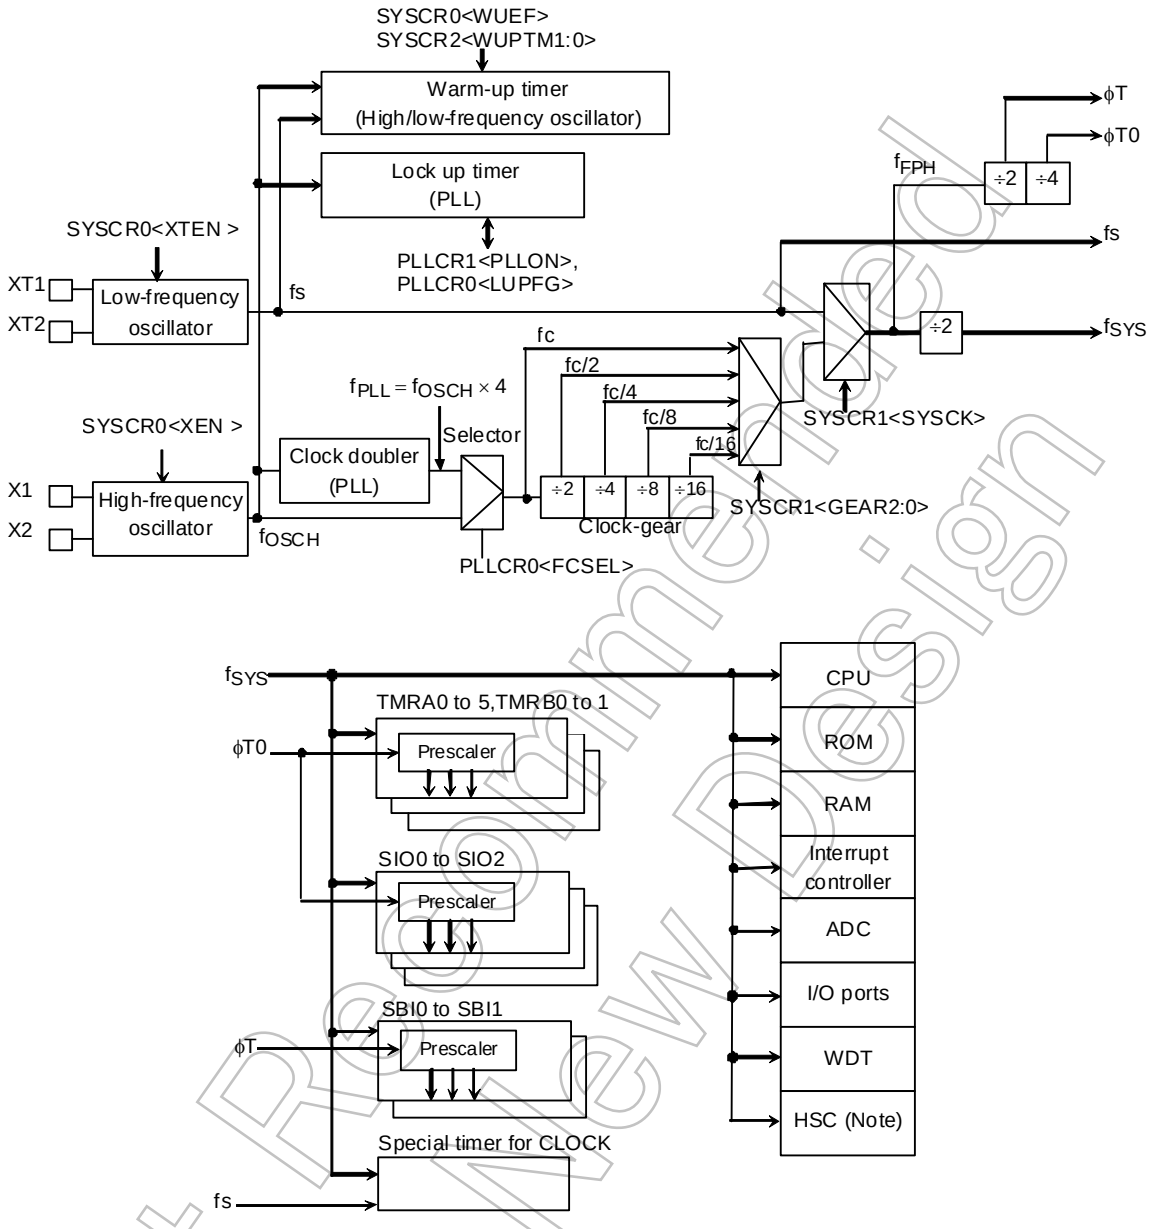
Note 3: It is not possible to shift from NORMAL mode with use of PLL to STOP mode directly.

NORMAL mode should be set once before shifting to STOP mode. (Stop the high-frequency oscillator after stopping PLL.)

Figure 3.3.1 System Clock Block Diagram

The clock frequency input from the X1 and X2 pins is called f_{OSCH} and the clock frequency input from the XT1 and XT2 pins is called fs. The clock frequency selected by SYSCR1<SYSCK> is called the clock f_{FPH}. The system clock f_{SYS} is defined as the divided clock of f_{FPH}, and one cycle of f_{SYS} is defined as one state.

3.3.1 Block Diagram of System Clock



Note: This circuit is not built into TMP92CY23.

Figure 3.3.2 Block Diagram of System Clock

Frequency of external oscillator is 6 to 10MHz. Don't connect oscillator more than 10MHz. (TMP92CD23A only)

3.3.2 SFR

SYSCR0 (10E0H)

	7	6	5	4	3	2	1	0

3.3.3 System Clock Controller

The system clock controller generates the system clock signal (f_{SYS}) for the CPU core and internal I/O. It contains two oscillation circuits and a clock gear circuit for high-frequency (fc) operation. The register SYSCR1<SYSCK> changes the system clock to either fc or fs, SYSCR0<XEN> and SYSCR0<XTEN> control enabling and disabling of each oscillator, and SYSCR1<GEAR2:0> sets the high-frequency clock gear to either 1, 2, 4, 8 or 16 (fc, fc/2, fc/4, fc/8 or fc/16). These functions can reduce the power consumption of the equipment in which the device is installed.

The combination of settings <XEN> = "1", <SYSCK> = "0" and <GEAR2:0> = "100" will cause the system clock (f_{SYS}) to be set to fc/32 (fc/16 × 1/2) after reset.

For example, f_{SYS} is set to 0.3125 MHz when the 10 MHz oscillator is connected to the X1 and X2 pins.

(1) Switching from normal mode to slow mode

When the resonator is connected to the X1 and X2 pins, or to the XT1 and XT2 pins, the warm-up timer can be used to change the operation frequency after stable oscillation has been attained.

The warm-up time can be selected using SYSCR2<WUPTM1:0>.

This warm-up timer can be programmed to start and stop as shown in the following examples 1 and 2.

Table 3.3.1 shows the warm-up time.

Note 1: When using an oscillator (other than a resonator) with stable oscillation, a warm-up timer is not needed.

Note 2: The warm-up timer is operated by an oscillation clock. Hence, there may be some variation in warm-up time.

Table 3.3.1 Warm-up Times

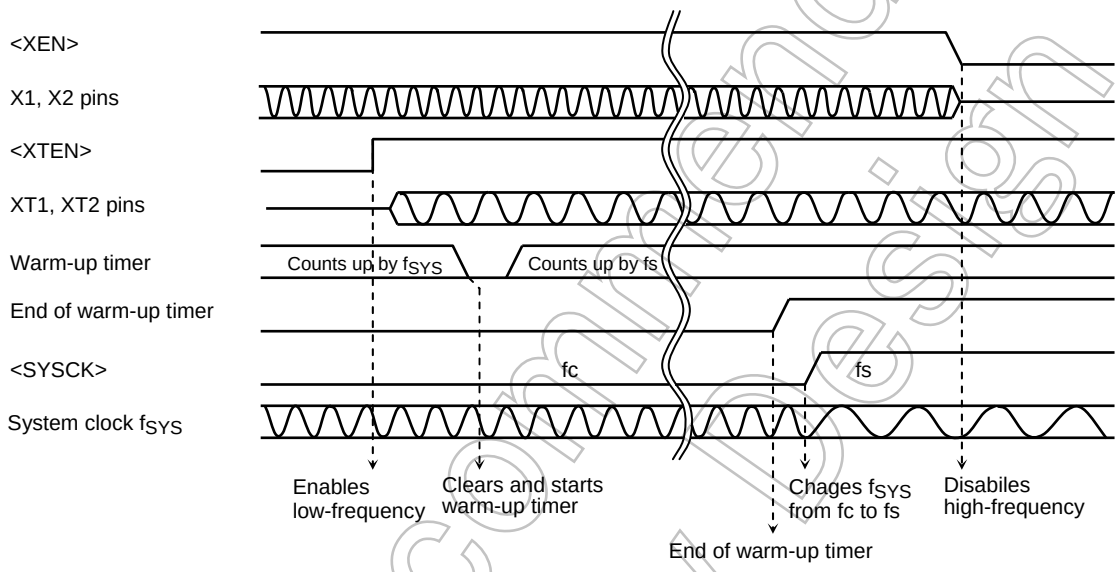
at f_{OSCH} = 10 MHz, fs = 32.768 kHz

Warm-up Time SYSCR2 <WUPTM1:0>	Change to Normal Mode	Change to Slow Mode
01 (2^8/frequency)	25.6 (μs)	7.8 (ms)
10 (2^{14}/frequency)	1.638 (ms)	500 (ms)
11 (2^{16}/frequency)	6.554 (ms)	2000 (ms)

Example 1: Setting the clock
Changing from high-frequency (fc) to low-frequency (fs).

```
SYSCR0   EQU   10E0H
SYSCR1   EQU   10E1H
SYSCR2   EQU   10E2H
         LD    (SYSCR2),  0 X 1 1 – – X – B  ;  Sets warm-up time to 2^16/fs.
         SET   6, (SYSCR0)                   ;  Enables low-frequency oscillation.
         SET   2, (SYSCR0)                   ;  Clears and starts warm-up timer.
WUP:     BIT   2, (SYSCR0)                   ;
         JR    NZ, WUP                       ;  Detects stopping of warm-up timer.
         SET   3, (SYSCR1)                   ;  Changes f_SYS from fc to fs.
         RES   7, (SYSCR0)                   ;  Disables high-frequency oscillation.
```

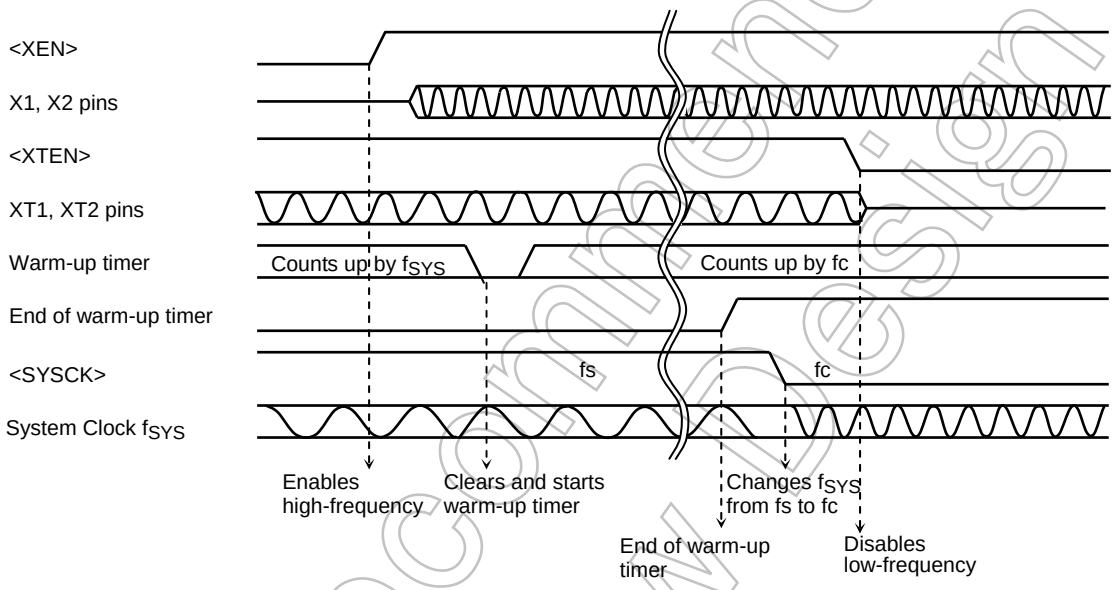
X: Don't care, –: No change



Example 2: Setting the clock
Changing from low-frequency (fs) to high-frequency (fc).

```
SYSCR0   EQU   10E0H
SYSCR1   EQU   10E1H
SYSCR2   EQU   10E2H
         LD    (SYSCR2), 0 X 1 0 – – X – B ;  Sets warm-up time to 2^14/fc.
         SET   7, (SYSCR0)                 ;  Enables high-frequency oscillation.
         SET   2, (SYSCR0)                 ;  Clears and starts warm-up timer.
WUP:     BIT   2, (SYSCR0)                 ;  } Detects stopping of warm-up timer.
         JR    NZ, WUP                     ;  }
         RES   3, (SYSCR1)                 ;  Changes f_SYS from fs to fc.
         RES   6, (SYSCR0)                 ;  Disables low-frequency oscillation.
```

X: Don't care, –: No change



(2) Clock gear controller

f_{FPH} is set according to the contents of the clock gear select register SYSCR1<GEAR2:0> to either fc, fc/2, fc/4, fc/8 or fc/16. Using the clock gear to select a lower value of f_{FPH} reduces power consumption.

Example 3: Changing to a high-frequency gear

```
SYSCR1    EQU    10E1H

          LD     (SYSCR1), XXXX0001B    ;    Changes fSYS to fc/2.
```

X: Don't care

(High-speed clock gear changing)

To change the clock gear, write the register value to the SYSCR1<GEAR2:0> register.It is necessary for the warm-up time to elapse before the change occurs after writing the register value.

There is the possibility that the instruction following the clock gear changing instruction is executed by the clock gear before changing.To execute the instruction following the clock gear switching instruction by the clock gear after changing, input the dummy instruction as follows (instruction to execute the write cycle).

Example:

```
SYSCR1    EQU    10E1H
          LD     (SYSCR1), XXXX0010B    ;    Changes fSYS to fc/4.
          LD     (DUMMY), 00H           ;    Dummy instruction
          Instruction to be executed after clock gear has changed
```

3.3.4 Clock Doubler (PLL)

PLL outputs the f_{PLL} clock signal, which is four times as fast as f_{OSCH}. A low-speed-frequency oscillator can be used, even though the internal clock is high-frequency.

A reset initializes PLL to stop status, so setting to PLLCR0, PLLCR1 register is needed before use.

As with an oscillator, this circuit requires time to stabilize. This is called the lock up time and it is measured by a 16-stage binary counter. Lock up time is about 1.6 ms at f_{OSCH} = 10 MHz.

Note 1: Input frequency range for PLL

The input frequency range (High-frequency oscillation) for PLL is as follows:

f_{OSCH} = 6 to 10 MHz (V_{CC} = 3.0 to 3.6 V)

Note 2: PLLCR0<LUPFG>

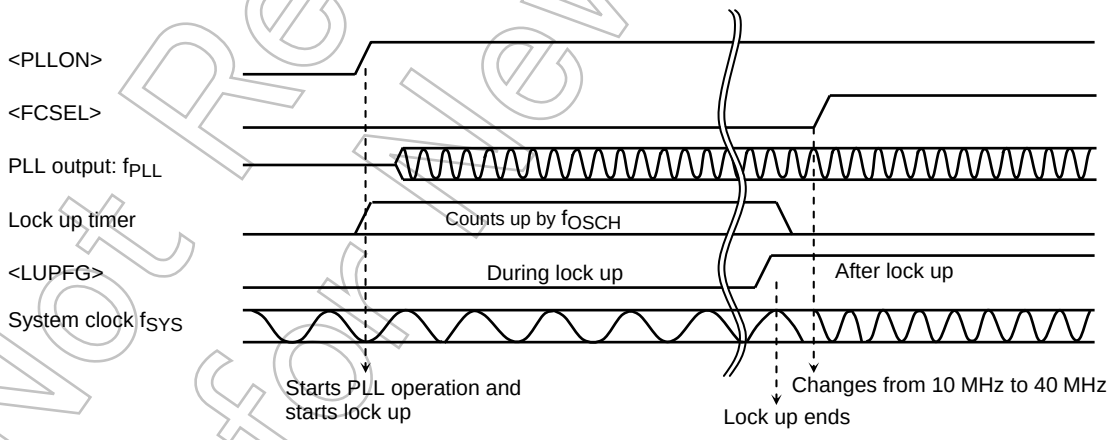
The logic of PLLCR0<LUPFG> is different from 900/L1's DFM.

Exercise care in determining the end of lock up time.

The following is an example of settings for PLL starting and PLL stopping.

Example 1: PLL starting

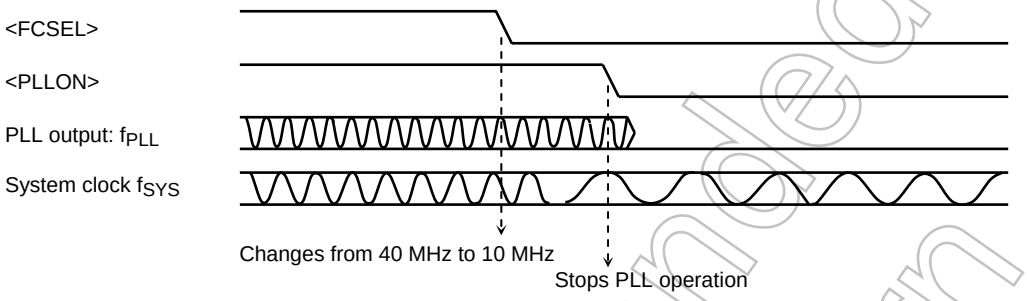
```
PLLCR0      EQU     10E8H
PLLCR1      EQU     10E9H
            LD      (PLLCR1),   1 X X X X X X X B ;  Enables PLL operation and starts lock up.
LUP:        BIT     5, (PLLCR0)                   ;
            JR      Z, LUP                        ;  Detects end of lock up.
            LD      (PLLCR0),   X 1 X X X X X X B ;  Changes fc from 10 MHz to 40 MHz.
X: Don't care
```



Example 2: PLL stopping

```
PLLCR0    EQU    10E8H
PLLCR1    EQU    10E9H
          LD     (PLLCR0), X0XXXXXXB    ;   Changes fc from 40 MHz to10 MHz.
          LD     (PLLCR1), 0XXXXXXXB    ;   Stop PLL.
```

X: Don't care



Limitations on the use of PLL

1. It is not possible to execute PLL enable/disable control in the SLOW mode (fs) (writing to PLLCR0 and PLLCR1).
   PLL should be controlled in the NORMAL mode.

2. When stopping PLL operation during PLL use, execute the following settings in the same order.

```
LD    (PLLCR0), 00H    ;  Change the clock fPLL to fOSCH
LD    (PLLCR1), 00H    ;  PLL stop
```

3. When stopping the high-frequency oscillator during PLL use, stop PLL before stopping the high-frequency oscillator.

Examples of settings are shown below:

(1) Start up/change control

(OK) Low-frequency oscillator operation mode (fs) (high-frequency oscillator STOP) → High-frequency oscillator start up → High-frequency oscillator operation mode (f_{OSCH}) → PLL start up → PLL use mode (f_{PLL})

```
      LD    (SYSCR0),  1 1 – – – 1 – – B ;  High-frequency oscillator start/warm-up start
WUP:  BIT   2, (SYSCR0)                 ;  } Check for warm-up end flag
      JR    NZ, WUP                     ;  }
      LD    (SYSCR1),  – – – – 0 – – – B ;  Change the system clock fs to fOSCH
      LD    (PLLCR1),  1 – – – – – – – B ;  PLL start-up/lock up start
LUP:  BIT   5, (PLLCR0)                 ;  } Check for lock up end flag
      JR    Z, LUP                      ;  }
      LD    (PLLCR0),  – 1 – – – – – – B ;  Change the system clock fOSCH to fPLL
```

(OK) Low-frequency oscillator operation mode (fs) (high-frequency oscillator Operate) → High-frequency oscillator operation mode (f_{OSCH}) → PLL start up → PLL use mode (f_{PLL})

```
      LD    (SYSCR1),  – – – – 0 – – – B ;  Change the system clock fs to fOSCH
      LD    (PLLCR1),  1 – – – – – – – B ;  PLL start-up/lock up start
LUP:  BIT   5, (PLLCR0)                 ;  } Check for lock up end flag
      JR    Z, LUP                      ;  }
      LD    (PLLCR0),  – 1 – – – – – – B ;  Change the system clock fOSCH to fPLL
```

(Error) Low-frequency oscillator operation mode (fs) (high-frequency oscillator STOP) → High-frequency oscillator start up → PLL start up → PLL use mode (f_{PLL})

```
      LD    (SYSCR0),  1 1 – – – 1 – – B ;  High-frequency oscillator start/warm-up start
WUP:  BIT   2, (SYSCR0)                 ;  } Check for warm-up end flag
      JR    NZ, WUP                     ;  }
      LD    (PLLCR1),  1 – – – – – – – B ;  PLL start-up/lock up start
LUP:  BIT   5, (PLLCR0)                 ;  } Check for lock up end flag
      JR    Z, LUP                      ;  }
      LD    (PLLCR0),  – 1 – – – – – – B ;  Change the internal clock fOSCH to fPLL
      LD    (SYSCR1),  – – – – 0 – – – B ;  Change the system clock fs to fPLL
```

(2) Change/stop control

(OK) PLL use mode (f_{PLL}) → High-frequency oscillator operation mode (f_{OSCH}) → PLL Stop → Low-frequency oscillator operation mode (fs) → High-frequency oscillator stop

```
LD    (PLLCR0),   – 0 – – – – – – B ;  Change the system clock fPLL to fOSCH
LD    (PLLCR1),   0 – – – – – – – B ;  PLL stop
LD    (SYSCR1),   – – – – 1 – – – B ;  Change the system clock fOSCH to fs
LD    (SYSCR0),   0 – – – – – – – B ;  High-frequency oscillator stop
```

(Error) PLL use mode (f_{PLL}) → Low-frequency oscillator operation mode (fs) → PLL stop → High-frequency oscillator stop

```
LD    (SYSCR1),   – – – – 1 – – – B ;  Change the system clock fPLL to fs
LD    (PLLCR0),   – 0 – – – – – – B ;  Change the internal clock (fc) fPLL to fOSCH
LD    (PLLCR1),   0 – – – – – – – B ;  PLL stop
LD    (SYSCR0),   0 – – – – – – – B ;  High-frequency oscillator stop
```

(OK) PLL use mode (f_{PLL}) → Set the STOP mode → High-frequency oscillator operation mode (f_{OSCH}) → PLL stop → Halt (High-frequency oscillator stop)

```
LD    (SYSCR2),   – – – 0 1 – – B ;  Set the STOP mode
                                     (This command can be executed before use of PLL)
LD    (PLLCR0),   – 0 – – – – – – B ;  Change the system clock fPLL to fOSCH
LD    (PLLCR1),   0 – – – – – – – B ;  PLL stop
HALT                               ;  Shift to STOP mode
```

(Error) PLL use mode (f_{PLL}) → Set the STOP mode → Halt (High-frequency oscillator stop)

```
LD    (SYSCR2),   – – – – 0 1 – – B ;  Set the STOP mode
                                       (This command can execute before use of PLL)
HALT                               ;  Shift to STOP mode
```

3.3.5 Noise Reduction Circuits

Noise reduction circuits are built-in, allowing implementation of the following features.

(1) Reduced drivability for low-frequency oscillator

(2) Reduced drivability for low-frequency oscillator (Note)

(3) SFR protection of register contents

Note: This function can use only TMP92CY23.

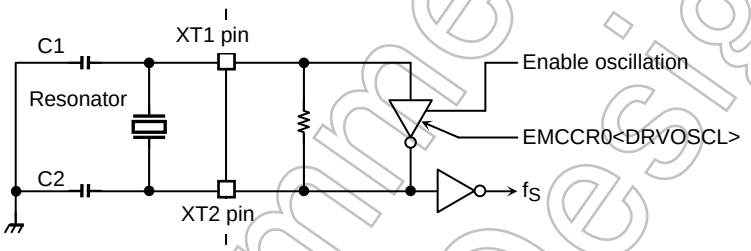
These functions need a setup by EMCCR0, EMCCR1, and EMCCR2 register.

(1) Reduced drivability for low-frequency oscillator

(Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)



(Setting method)

The drive ability of the oscillator is reduced by writing "0" to the EMCCR0<DRVOSCL> register. At reset, <DRVOSCL> is initialized to "1" and the oscillator starts oscillation by normal drivability when the power-supply is on.

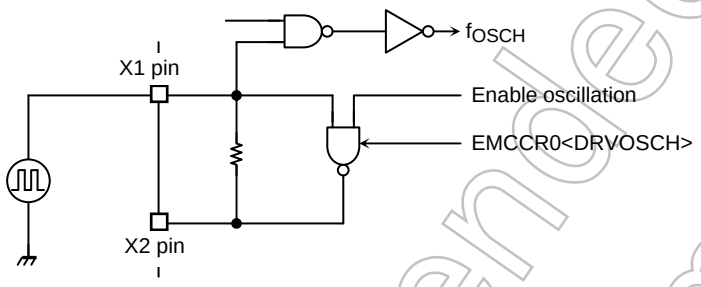
(2) Single drive for high-frequency oscillator (Note)

(Purpose)

Remove the need for twin drives and prevent operational errors caused by noise input to X2 pin when an external oscillator is used.

Note: This function can use only TMP92CY23.

(Block diagram)



(Setting method)

The oscillator is disabled and starts operation as buffer by writing "1" to EMCCR0<EXTIN> register. X2 pin's output is always "1".

At reset, <EXTIN> is initialized to "0".

Note: Do not write EMCCR0<EXTIN> = "1" when using external resonator.

(2) Runaway prevention using SFR protection register

(Purpose)

Prevention of program runaway caused by introduction of noise.

Write operations to a specified SFR are prohibited so that the program is protected from runaway caused by stopping of the clock or by changes to the memory control register (memory controller) which prevent fetch operations.

Runaway error handling is also facilitated by INTP0 interruption.

Specified SFR list

1. Memory controller
   B0CSL/H, B1CSL/H, B2CSL/H, B3CSL/H, BEXCSL/H
   MSAR0, MSAR1, MSAR2, MSAR3,
   MAMR0, MAMR1, MAMR2, MAMR3, PMEMCR
2. Clock gear
   SYSCR0, SYSCR1, SYSCR2, EMCCR0
4. PLL
   PLLCR0, PLLCR1

(Operation explanation)

Execute and release of protection (write operation to specified SFR) becomes possible by setting up a double key to EMCCR1 and EMCCR2 registers.

(Double key)

1st KEY: writes in sequence, 5AH at EMCCR1 and A5H at EMCCR2

2nd KEY: writes in sequence, A5H at EMCCR1 and 5AH at EMCCR2

Protection state can be confirmed by reading EMCCR0<PROTECT>.

At reset, protection becomes OFF.

INTP0 interruption also occurs when a write operation to the specified SFR is executed with protection in the ON state.

3.3.6 Stand-by Controller

(1) HALT modes and port drive register

When the HALT instruction is executed, the operating mode switches to IDLE2, IDLE1 or STOP mode, depending on the contents of the SYSCR2<HALTM1:0> register.

The subsequent actions performed in each mode are as follows:

1. IDLE2: only the CPU halts.

   The internal I/O is available to select operation during IDLE2 mode by setting the following register.

   Table 3.3.2 shows the register setting operation during IDLE2 mode.

Table 3.3.2 SFR Setting Operation during IDLE2 Mode

Internal I/O	SFR
TMRA01	TA01RUN<I2TA01>
TMRA23	TA23RUN<I2TA23>
TMRA45	TA45RUN<I2TA45>
TMRB0	TB0RUN<I2TB0>
TMRB1	TB1RUN<I2TB1>
SIO0	SC0MOD1<I2S0>
SIO1	SC1MOD1<I2S1>
SIO2	SC2MOD1<I2S2>
AD converter	ADMOD1<I2AD>
WDT	WDMOD<I2WDT>
SBI0	SBI0BR0<I2SBI0>
SBI1	SBI1BR0<I2SBI1>

2. IDLE1: Only the oscillator and the Special timer for CLOCK continue to operate.
3. STOP: All internal circuits stop operating.

The operation of each of the different HALT modes is described in Table 3.3.3.

Table 3.3.3 I/O Operation during HALT Modes

<table>
<tr><th colspan="2">HALT Mode</th><th>IDLE2</th><th>IDLE1</th><th>STOP</th></tr>
<tr><td colspan="2">SYSCR2<HALTM1:0></td><td>11</td><td>10</td><td>01</td></tr>
<tr><td rowspan="10">Block</td><td>CPU</td><td colspan="3">Stop</td></tr>
<tr><td>I/O ports</td><td>The state at the time of "HALT" instruction execution is held.</td><td colspan="2">Table 3.3.7 and Table 3.3.8 references</td></tr>
<tr><td>TMRA, TMRB</td><td rowspan="4">Available to select operation block</td><td rowspan="5" colspan="2">Stop</td></tr>
<tr><td>SIO, SBI</td></tr>
<tr><td>AD converter</td></tr>
<tr><td>WDT</td></tr>
<tr><td>Interrupt controller</td><td rowspan="3">Operate</td></tr>
<tr><td>HSC (Note)</td></tr>
<tr><td>Special timer for CLOCK</td><td>Operate</td></tr>
</table>

Note: This circuit is not built into TMP92CY23.

(2) How to release the HALT mode

These halt states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combination of the states of the interrupt mask register <IFF2:0> and the HALT modes. The details for releasing the halt status are shown in Table 3.3.4.

Release by interrupt requesting

The HALT mode release method depends on the status of the enabled interrupt .When the interrupt request level set before executing the HALT instruction exceeds the value of the interrupt mask register, the interrupt is processed depending on its status after the HALT mode is released, and the CPU status executing the instruction that follows the HALT instruction. When the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register, HALT mode release is not executed. (in non-maskable interrupts, interrupt processing is processed after releasing the HALT mode regardless of the value of the mask register.) However only for INT0 to INT7, INTRTC interrupts, even if the interrupt request level set before executing the halt instruction is less than the value of the interrupt mask register, HALT mode release is executed. In this case, the interrupt is processed, and the CPU starts executing the instruction following the HALT instruction, but the interrupt request flag is held at "1".

Release by resetting

Release of all halt statuses is executed by resetting.

When the STOP mode is released by RESET, it is necessary to allow enough resetting time (see Table 3.3.5) for operation of the oscillator to stabilize.

When releasing the HALT mode by resetting, the internal RAM data keeps the state before the HALT instruction is executed. However the other settings contents are initialized. (Releasing due to interrupts keeps the state before the HALT instruction is executed.)

Table 3.3.4 Source of Halt State Clearance and Halt Clearance Operation

Status of Received Interrupt			Interrupt Enabled (Interrupt level) ≥ (Interrupt mask)			Interrupt Disabled (Interrupt level) < (Interrupt mask)		
HALT Mode			IDLE2	IDLE1	STOP	IDLE2	IDLE1	STOP
Source of Halt State Clearance	Interrupt	NMI	♦	♦	♦*1	–	–	–
		INTWDT	♦	×	×	–	–	–
		INT0 to INT4, INT7 (Note 1)	♦	♦	♦*1	○	○	○*1
		INT5,INT6 (PORT) (Note 1)	♦	♦	♦*1	○	○	○*1
		INT5,INT6 (TMRB1)	♦	×	×	×	×	×
		INTTA0 to INTTA5	♦	×	×	×	×	×
		INTB00, INTTB01, INTTB10, INTTB11, INTTBO0, INTTBO1	♦	×	×	×	×	×
		INTRX0 to INTRX2, INTTX0 to INTTX2	♦	×	×	×	×	×
		INTAD	♦	×	×	×	×	×
		KWI	♦	♦	♦*1	Δ	Δ	Δ
		INTRTC	♦	♦	×	○	○	×
		INTSBE0 to INTSBE1	♦	×	×	×	×	×
		INTHSC (Note4)	♦	×	×	×	×	×
	RESET		Initialize LSI					

♦: After clearing the HALT mode, CPU starts interrupt processing.

○: After clearing the HALT mode, CPU resumes executing starting from the instruction following the HALT instruction.

×: Cannot be used to release the HALT mode.

–: The priority level (interrupt request level) of non-maskable interrupts is fixed to 7, the highest priority level. This combination is not available.

Δ: Since KWI does not have a function as interruption, this combination does not exist.

*1: Release of the HALT mode is executed after warm-up time has elapsed.

Note 1: When the HALT mode is cleared by an INT0 to 7 interrupt of the level mode in the interrupt enabled status, hold level "H" until starting interrupt processing. If level "L" is set before holding level "L", interrupt processing is correctly started.

Note 2: Although a KWI can cancel all HALT mode states, the function as interruption does not have it.

Note 3: Specify the HSCSEL register when selecting INTTX1 or INTHSC interrupt with the same interrupt factor.

Note4: The INTHSC interrupt is not built into TMP92CY23.

Example: Releasing IDLE1 mode

An INT0 interrupt clears the halt state when the device is in IDLE1 mode.

```
Address
8200H    LD      (P7FC), 10H        ;  Sets P74 to INT0 interrupt.
8203H    LD      (IIMC3), 00H       ;  Selects INT0 interrupt rising edge.
8206H    LD      (IIMC2), 00H       ;  Selects INT0 interrupt edge
8209H    LD      (INTE01), 06H         Sets INT0 interrupt level to 6.
820BH    EI      5                  ;  Sets interrupt level to 5 for CPU.
820EH    LD      (SYSCR2), 28H      ;  Sets HALT mode to IDLE1 mode.
820FH    HALT                       ;  Halts CPU.
```

(3) Operation

1. IDLE2 mode

In IDLE2 mode only specific internal I/O operations, as designated by the IDLE2 setting register, can take place. Instruction execution by the CPU stops.

Figure 3.3.6 illustrates an example of the timing for clearance of the IDLE2 mode halt state by an interrupt.

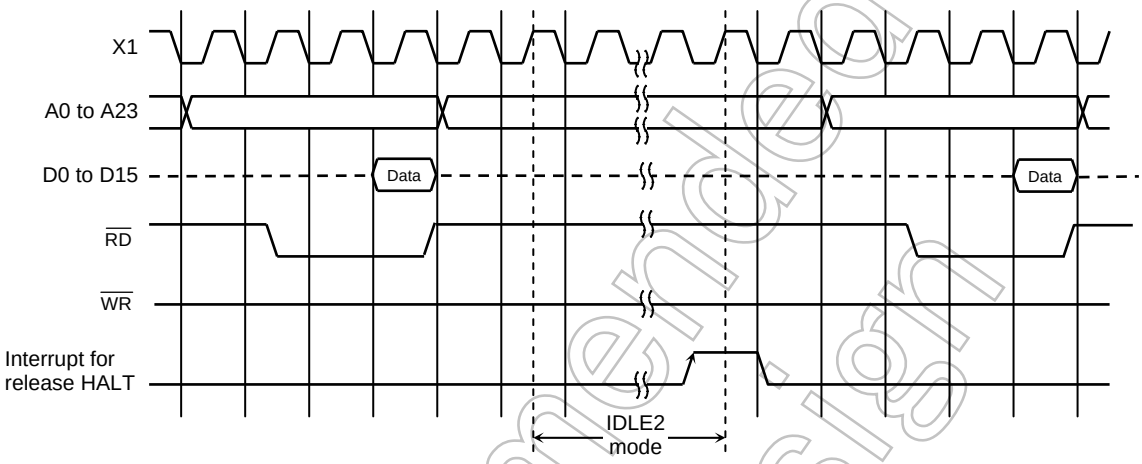


Figure 3.3.6 Timing Chart for IDLE2 Mode Halt State Cleared by Interrupt

2. IDLE1 mode

In IDLE1 mode, only the internal oscillator and Special timer for Clock continue to operate. The system clock stops.

In the halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the halt state (e.g., restart of operation) is synchronous with it.

Figure 3.3.7 illustrates the timing for clearance of the IDLE1 mode halt state by an interrupt.

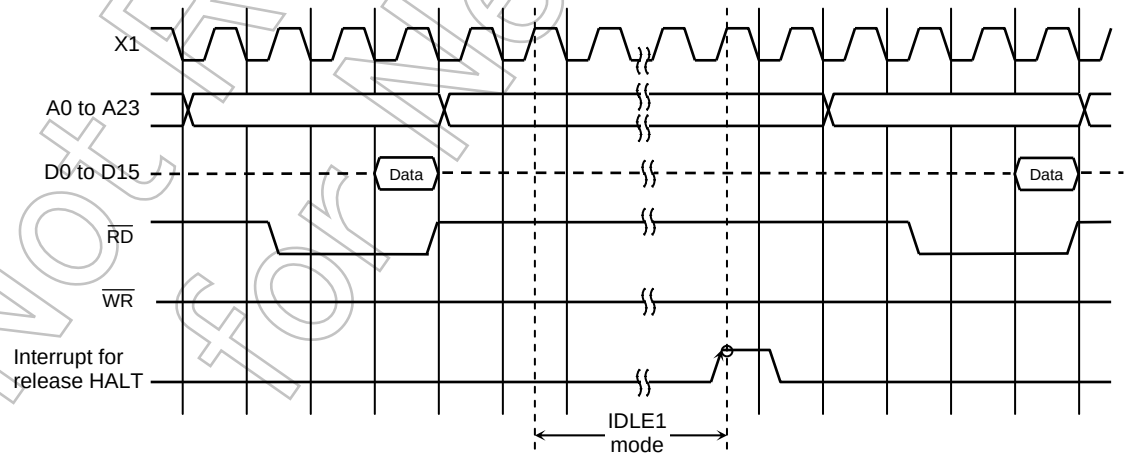

Figure 3.3.7 Timing Chart for IDLE1 Mode Halt State Cleared by Interrupt

3. STOP mode

When STOP mode is selected, all internal circuits stop, including the internal oscillator.

After STOP mode has been cleared system clock output starts when the warm-up time by the counter for a warm-up of internal oscillator and built-in FlashROM warm-up time.

The example of a setting of the Warm-up time at the time of STOP mode release is shown in Table 3.3.5. The warm-up time of built-in FlashROM is shown in Table 3.3.6.

Note: Although this product is a MaskROM product, in order to consider as the same operation as a FlashROM product, built-in FlashROM warm-up time enters.

Figure 3.3.8 illustrates the timing for clearance of the STOP mode halt state by an interrupt.

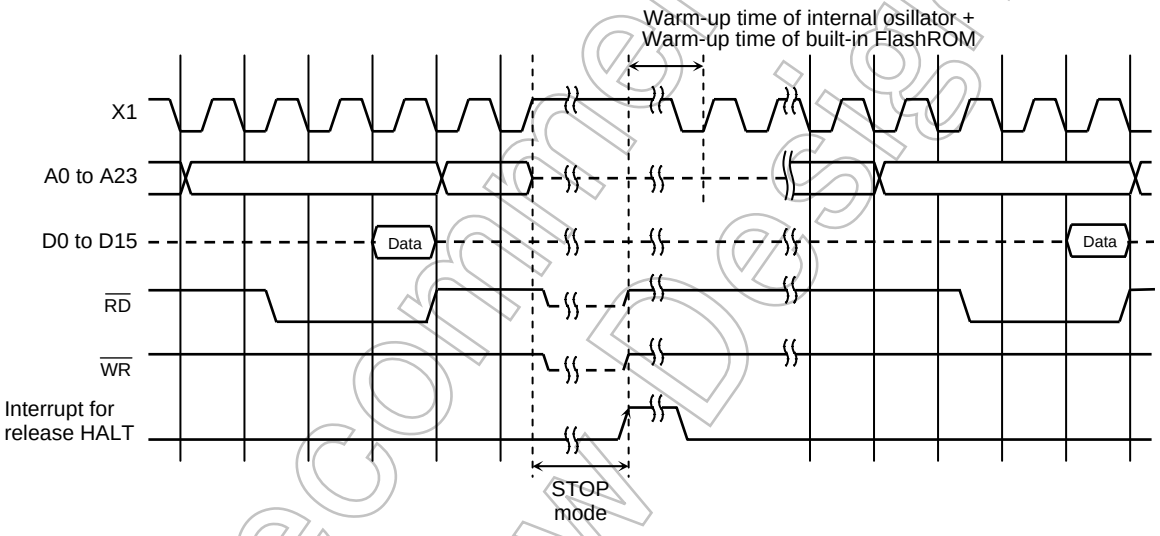

Figure 3.3.8 Timing Chart for STOP Mode Halt State Cleared by Interrupt

Table 3.3.5 Example of Warm-up Time after Releasing STOP Mode

at f_{OSCH} = 10 MHz, fs = 32.768 kHz

SYSCR1 <SYSCK>	SYSCR2<WUPTM1:0>		
	01 (2^8)	10 (2^{14})	11 (2^{16})
0 (fc)	25.6 μs	1.638 ms	6.554 ms
1 (fs)	7.8 ms	500 ms	2000 ms

Table 3.3.6 Example of Warm-up Time after Built-in FlashROM (at the time of STOP mode release)

at f_{OSCH} = 10 MHz, fs = 32.768 kHz

0 (fc)	409.6 μs ($2^{12}/f_{OSCH}$)
1 (fs)	125 ms (2^{12}/fs)

Table 3.3.7 Input Buffer State Table

Port Name	Input Function Name	Input Buffer State								
		During Reset	When the CPU is operating		In HALT mode (IDLE1/2)		In HALT mode (STOP)

X2	–	ON	–		–		OFF	–		–

ON: The buffer is always turned on. When the bus is released, however, output buffers for some pins are turned off.

OFF: The buffer is always turned off.

–: Not applicable

*1: ON upon external write.

*2: Port having a pull-up resistor (programmable)

*3: Open-Drain output pin.

*4: HSSO and HSCLK output functions are not built into TMP92CY23.

3.4 Interrupts

Interrupts are controlled by the CPU Interrupt mask register <IFF2:0> and by the built-in interrupt controller.

The TMP92CY23 has a total of 50 interrupts, TMP92CD23A has a total of 51 interrupts.

Interrupts generated by CPU: 9 sources
- Software interrupts: 8 sources
- Illegal instruction interrupt: 1 source

Internal interrupts: TMP92CY23: 32 sources, TMP92CD23A: 33 sources
- Internal I/O interrupts: TMP92CY23: 24 sources, TMP92CD23A: 25 sources
- Micro DMA transfer end interrupts: 8 sources

External interrupts: 9 sources
- Interrupts on external pins (INT0 to INT7, $\overline{\text{NMI}}$)

A fixed individual interrupt vector number is assigned to each interrupt source.

Any one of six levels of priority can also be assigned to each maskable interrupt. Non-maskable interrupts have a fixed priority level of 7, the highest level.

When an interrupt is generated, the interrupt controller sends the priority of that interrupt to the CPU. When more than one interrupt is generated simultaneously, the interrupt controller sends the priority value of the interrupt with the highest priority to the CPU. (The highest priority level is 7, the level used for non-maskable interrupts.)

The CPU compares the interrupt priority level which it receives with the value held in the CPU interrupt mask register <IFF2:0>. If the priority level of the interrupt is greater than or equal to the value in the interrupt mask register, the CPU accepts the interrupt.

However, software interrupts and illegal instruction interrupts generated by the CPU are processed irrespective of the value in <IFF2:0>.

The value in the interrupt mask register <IFF2:0> can be changed using the EI instruction (EI num sets <IFF2:0> to num). For example, the command EI 3 enables the acceptance of all non-maskable interrupts and of maskable interrupts whose priority level, as set in the interrupt controller, is 3 or higher. The commands EI and EI 0 enable the acceptance of all non-maskable interrupts and of maskable interrupts with a priority level of 1 or above (hence both are equivalent to the command EI 1).

The DI instruction (sets <IFF2:0> to 7) is exactly equivalent to the EI 7 instruction. The DI instruction is used to disable all maskable interrupts (since the priority level for maskable interrupts ranges from 1 to 6). The EI instruction takes effect as soon as it is executed.

In addition to the general purpose interrupt processing mode described above, there is also a micro DMA processing mode.

In micro DMA mode the CPU automatically transfers data in one-byte, two-byte or four-byte blocks; this mode allows high-speed data transfer to and from internal and external memory and internal I/O ports.

In addition, the TMP92CY23/CD23A also has a software start function in which micro DMA processing is requested in software rather than by an interrupt.

Figure 3.4.1 is a flowchart showing overall interrupt processing.

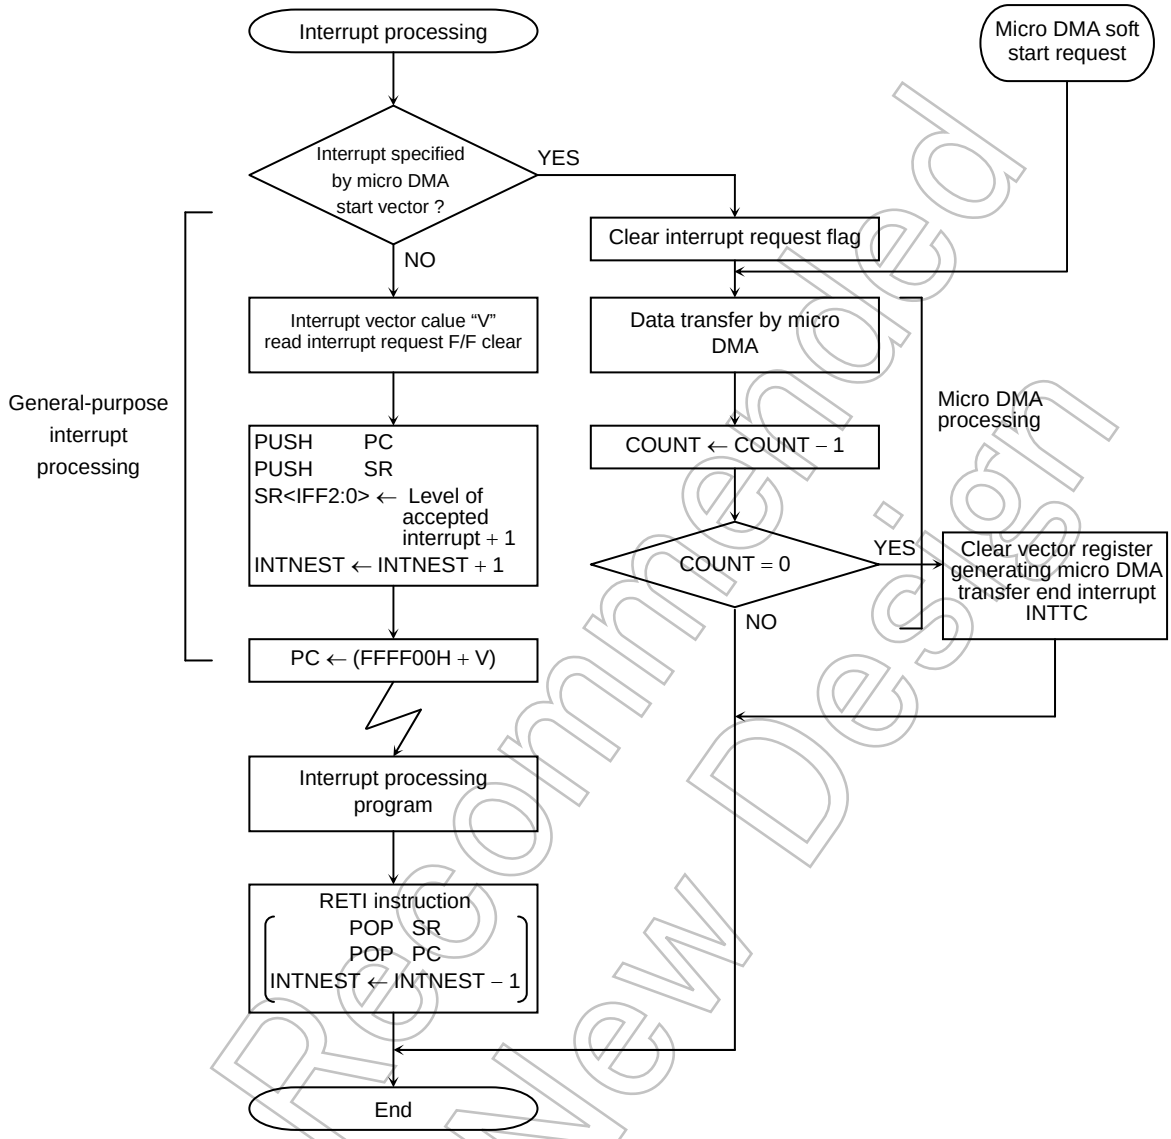

Figure 3.4.1 Interrupt and Micro DMA Processing Sequence

3.4.1 General-purpose Interrupt Processing

When the CPU accepts an interrupt, it usually performs the following sequence of operations. However, in the case of software interrupts and illegal instruction interrupts generated by the CPU, the CPU skips steps (1) and (3), and executes only steps (2), (4) and (5).

(1) The CPU reads the interrupt vector from the interrupt controller.

When more than one interrupt with the same priority level has been generated simultaneously, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt requests.

(The default priority is determined as follows: the smaller the vector value, the higher the priority.)

(2) The CPU pushes the program counter (PC) and status register (SR) onto the top of the stack (pointed to by XSP).

(3) The CPU sets the value of the CPU's interrupt mask register <IFF2:0> to the priority level for the accepted interrupt plus 1. However, if the priority level for the accepted interrupt is 7, the register's value is set to 7.

(4) The CPU increments the interrupt nesting counter INTNEST by 1.

(5) The CPU jumps to the address given by adding the contents of address FFFF00H + the interrupt vector, then starts the interrupt processing routine.

On completion of interrupt processing, the RETI instruction is used to return control to the main routine. RETI restores the contents of the program counter and the status register from the stack and decrements the interrupt nesting counter INTNEST by 1.

Non-maskable interrupts cannot be disabled by a user program. Maskable interrupts, however, can be enabled or disabled by a user program. A program can set the priority level for each interrupt source. (A priority level setting of 0 or 7 will disable an interrupt request.)

If an interrupt request is received for an interrupt with a priority level equal to or greater than the value set in the CPU interrupt mask register <IFF2:0>, the CPU will accept the interrupt. The CPU interrupt mask register <IFF2:0> is then set to the value of the priority level for the accepted interrupt plus 1.

If during interrupt processing, an interrupt is generated with a higher priority than the interrupt currently being processed, or if, during the processing of a non-maskable interrupt processing, a non-maskable interrupt request is generated from another source, the CPU will suspend the routine which it is currently executing and accept the new interrupt. When processing of the new interrupt has been completed, the CPU will resume processing of the suspended interrupt.

If the CPU receives another interrupt request while performing processing steps (1) to (5), the new interrupt will be sampled immediately after execution of the first instruction of its interrupt processing routine. Specifying DI as the start instruction disables nesting of maskable interrupts.

A reset initializes the interrupt mask register <IFF2:0> to "111", disabling all maskable interrupts.

Table 3.4.1 shows the TMP92CY23/CD23A interrupt vectors and micro DMA start vectors. FFFF00H to FFFFFFH (256 bytes) is designated as the interrupt vector area.

Table 3.4.1 TMP92CY23/CD23A Interrupt Vectors and Micro DMA Start Vectors

Default Priority	Type	Interrupt Source and Source of Micro DMA Request	Vector Value	Address Refer to Vector	Micro DMA Start Vector
1	Non-maskable	Reset or [SWI0] instruction	0000H	FFFF00H

60		INTTC7: Micro DMA end (Channel 7)	00ECH	FFFFECH	3BH
– to –		(Reserved)	00F0H : 00FCH	FFFFF0H : FFFFFCH	– to –

Note 1: When initiating micro DMA, set at edge detect mode.

Note 2: Micro DMA default priority.
Micro DMA initiation takes priority over other maskable interrupts.

Note 3: Specify the HSCSEL register when selecting INTTX1 or INTHSC that have the same interrupt factor in the default priority 30.

Note4: The INTHSC interrupt is not built into TMP92CY23.

3.4.2 Micro DMA Processing

In addition to general purpose interrupt processing, the TMP92CY23/CD23A also includes a micro DMA function. Micro DMA processing for interrupt requests set by micro DMA is performed at the highest priority level for maskable interrupts (level 6), regardless of the priority level of the interrupt source.

Because the micro DMA function is implemented through the CPU, when the CPU is placed in a stand-by state by a Halt instruction, the requirements of the micro DMA will be ignored (pending).

Micro DMA supports 8 channels and can be transferred continuously by specifying the micro DMA burst function as below.

(1) Micro DMA operation

When an interrupt request is generated by an interrupt source specified by the micro DMA start vector register, the micro DMA triggers a micro DMA request to the CPU at interrupt priority level 6 and starts processing the request. The eight micro DMA channels allow micro DMA processing to be set for up to eight types of interrupt at once.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. Data in one-byte, two-byte or four-byte blocks, is automatically transferred at once from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented by 1. If the value of the counter after it has been decremented is not 0, DMA processing ends with no change in the value of the micro DMA start vector register. If the value of the decremented counter is 0, a micro DMA transfer end interrupt (INTTC0 to INTTC7) is sent from the CPU to the interrupt controller. In addition, the micro DMA start vector register is cleared to "0", the next micro DMA operation is disabled and micro DMA processing terminates.

If micro DMA requests are set simultaneously for more than one channel, priority is not based on the interrupt priority level but on the channel number: the lower the channel number, the higher the priority (channel 0 thus has the highest priority and channel 7 the lowest).

If an interrupt request is triggered for the interrupt source in use during the interval between the time at which the micro DMA start vector is cleared and the next setting, general purpose interrupt processing is performed at the interrupt level set. Therefore, if the interrupt is only being used to initiate micro DMA (and not as a general-purpose interrupt), the interrupt level should first be set to 0 (i.e., interrupt requests should be disabled).

If using micro DMA and general-purpose interrupts together, first set the level of the interrupt used to start micro DMA processing lower than all the other interrupt levels. (Note) In this case, the cause of general interrupt is limited to the edge interrupt.

The priority of the micro DMA transfer end interrupt (INTTC0 to INTTC3) is defined by the interrupt level and the default priority as the same as the other maskable interrupt.

Note: If the priority level of micro DMA is set higher than that of other interrupts, CPU operates as follows.
In case INTxxx interrupt is generated first and then INTyyy interrupt is generated between checking "Interrupt specified by micro DMA start vector" (in the Figure 3.4.1) and reading interrupt vector with setting below. The vector shifts to that of INTyyy at the time.
This is because the priority level of INTyyy is higher than that of INTxxx.
In the interrupt routine, CPU reads the vector of INTyyy because cheking of micro DMA has finished.
And INTyyy is generated regardless of transfer counter of micro DMA.
INTxxx: level 1 without micro DMA
INTyyy: level 6 with micro DMA

If micro DMA and general purpose interrupts are being used together as described above, the level of the interrupt which is being used to initiate micro DMA processing should first be set to a lower value than all the other interrupt levels. In this case, edge triggered interrupts are the only kinds of general interrupts which can be accepted.

Although the control registers used for setting the transfer source and transfer destination addresses are 32 bits wide, this type of register can only output 24-bit addresses. Accordingly, micro DMA can only access 16 Mbytes.

Three micro DMA transfer modes are supported: one-byte transfers, two-byte transfer and four-byte transfer. After a transfer in any mode, the transfer source and transfer destination addresses will either be incremented or decremented, or will remain unchanged. This simplifies the transfer of data from memory to memory, from I/O to memory, from memory to I/O, and from I/O to I/O. For details of the various transfer modes, see section 3.4.2 (4), detailed description of the transfer mode register.

Since a transfer counter is a 16-bit counter, up to 65536 micro DMA processing operations can be performed per interrupt source (provided that the transfer counter for the source is initially set to 0000H).

Micro DMA processing can be initiated by any one of 40 different interrupts – the 39 interrupts shown in the micro DMA start vectors in Table 3.4.1 and a micro DMA soft start.

Figure 3.4.2 shows a 2-byte transfer carried out using a micro DMA cycle in transfer destination address INC mode (micro DMA transfers are the same in every mode except counter mode). (The conditions for this cycle are as follows: this cycle is based on an external 8-bit bus, 0 waits, source/transfer destination addresses both even-numbered values.)

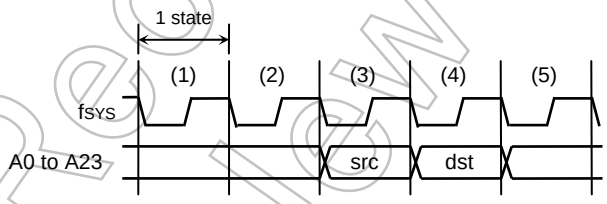

Figure 3.4.2 Timing for Micro DMA Cycle

State (1), (2): Instruction fetch cycle (Prefetches the next instruction code)
If the instruction queue buffer is FULL, this cycle becomes a dummy cycle.

State (3): Micro DMA read cycle

State (4): Micro DMA write cycle

State (5): (The same as in state (1), (2))

(2) Soft start function

The TMP92CY23/CD23A can initiate micro DMA either with an interrupt or by using the micro DMA soft start function, in which micro DMA is initiated by a write cycle which writes to the register DMAR.

Writing "1" to any bit of the register DMAR causes micro DMA to be performed once (If write "0" to each bit, micro DMA doesn't operate). On completion of the transfer, the bits of DMAR which support the end channel are automatically cleared to "0".

Only one channel can be set for DMA request at once. (Do not write "1" to plural bits)

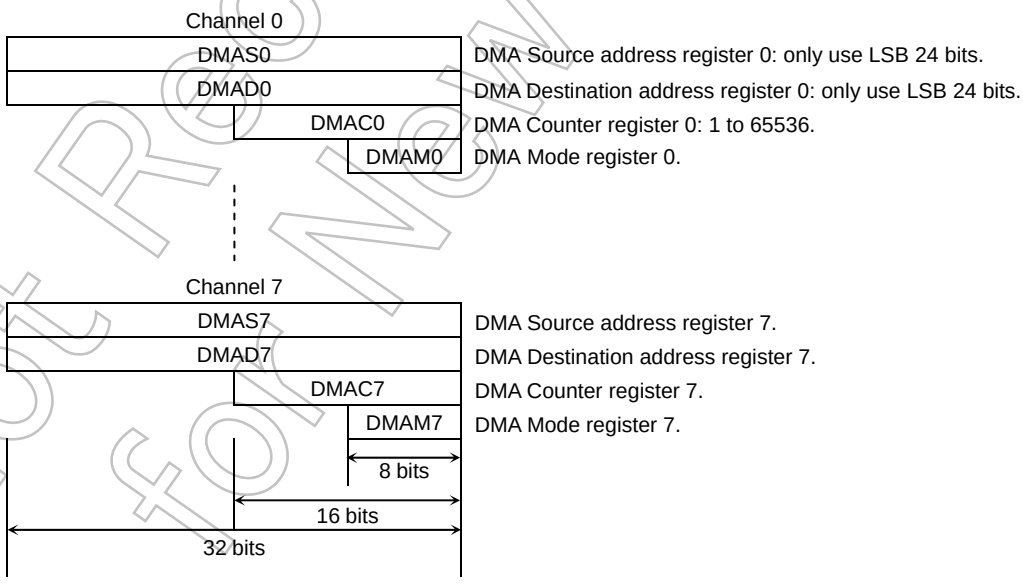
When writing again "1" to the DMAR register, check whether the bit is 0 before writing 1. If read "1", micro DMA transfer isn't started yet.

When a burst is specified by the register DMAB, data is transferred continuously from the initiation of micro DMA until the value in the micro DMA transfer counter is "0" after start up of the micro DMA. If execute soft start during micro DMA transfer by interrupt source, micro DMA transfer counter doesn't change. Don't use Read-modify-write instruction to avoid writing to other bits by mistake.

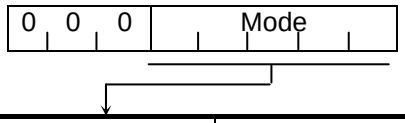
Symbol	Name	Address	7	6	5	4	3	2	1	0
DMAR	DMA Request	109H (Prohibit RMW)	DREQ7	DREQ6	DREQ5	DREQ4	DREQ3	DREQ2	DREQ1	DREQ0
			R/W							
			0	0	0	0	0	0	0	0
			1: DMA request in software							

(3) Transfer control registers

The transfer source address and the transfer destination address are set in the following registers. An instruction of the form LDC cr, r can be used to set these registers.



(4) Detailed description of the transfer mode register



DMAMn[4:0]	Mode Description	Execution State Number
0 0 0 z z	Destination INC mode (DMADn+) ← (DMASn) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
0 0 1 z z	Destination DEC mode (DMADn–) ← (DMASn) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
0 1 0 z z	Source INC mode (DMADn) ← (DMASn+) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
0 1 1 z z	Source DEC mode (DMADn) ← (DMASn–) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
1 0 0 z z	Source and destination INC mode (DMADn+) ← (DMASn+) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	6 states
1 0 1 z z	Source and destination DEC mode (DMADn–) ← (DMASn–) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	6 states
1 1 0 z z	Source and destination Fixed mode (DMADn) ← (DMASn) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
1 1 1 0 0	Counter mode DMASn ← DMASn + 1 DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states

ZZ: 00 = 1-byte transfer
01 = 2-byte transfer
10 = 4-byte transfer
11 = (Reserved)

Note1: The execution state number shows number of best case (1-state memory access). 1state = 50ns at f_{SYS} = 20MHz

Note2: N stands for the micro DMA channel number (0 to 7)
DMADn+/DMASn+: Post-increment (register value is incremented after transfer)
DMADn–/DMASn–: Post-decrement (register value is decremented after transfer)
"I/O" signifies fixed memory addresses; "memory" signifies incremented or decremented memory addresses.

Note3: The transfer mode register should not be set to any value other than those listed above.

3.4.3 Interrupt Controller Operation

The block diagram in Figure 3.4.3 shows the interrupt circuits. The left hand side of the diagram shows the interrupt controller circuit. The right hand side shows the CPU interrupt request signal circuit and the halt release circuit.

For each of the 50 interrupts channels there is an interrupt request flag (consisting of a flip-flop), an interrupt priority setting register and a micro DMA start vector register.

The interrupt request flag latches interrupt requests from the peripherals. The flag is cleared to "0" in the following cases: when a reset occurs, when the CPU reads the channel vector of an interrupt it has received, when the CPU receives a micro DMA request (when micro DMA is set), when a micro DMA burst transfer is terminated, and when an instruction that clears the interrupt for that channel is executed (by writing a micro DMA start vector to the INTCLR register).

An interrupt priority can be set independently for each interrupt source by writing the priority to the interrupt priority setting register (e.g., INTEPAD or INTE01). 6 interrupt priorities levels (1 to 6) are provided. Setting an interrupt source's priority level to 0 (or 7) disables interrupt requests from that source. The priority of non-maskable interrupt (watchdog timer interrupts) is fixed at 7.

If more than one interrupt request with a given priority level are generated simultaneously, the default priority (the interrupt with the lowest priority or, in other words, the interrupt with the lowest vector value) is used to determine which interrupt request is accepted first.

The 3rd and 7th bit of the interrupt priority setting register indicate the state of the interrupt request flag and thus whether an interrupt request for a given channel has occurred.

If several interrupts are generated simultaneously, the interrupt controller sends the interrupt request for the interrupt with the highest priority and the interrupt's vector address to the CPU. The CPU compares the mask value set in <IFF2:0> of the status register (SR) with the priority level of the requested interrupt; if the latter is higher, the interrupt is accepted. Then the CPU sets SR<IFF2:0> to the priority level of the accepted interrupt + 1. Hence, during processing of the accepted interrupt, new interrupt requests with a priority value equal to or higher than the value set in SR<IFF2:0> (e.g., interrupts with a priority higher than the interrupt being processed) will be accepted.

When interrupt processing has been completed (e.g., after execution of a RETI instruction), the CPU restores to SR<IFF2:0> the priority value which was saved on the stack before the interrupt was generated.

The interrupt controller also includes eight registers which are used to store the micro DMA start vector. Writing the start vector of the interrupt source for the micro DMA processing (see Table 3.4.1), enables the corresponding interrupts to be processed by micro DMA processing. The values must be set in the micro DMA parameter registers (e.g., DMAS and DMAD) prior to micro DMA processing.

			Clear the interrupt request flag by the writing of a micro DMA starting vector							

Note 1: Disable INT0 to INT7 requests before changing INT0 to INT7 pins mode from level sense to edge sense.

Setting example for case of INT0:

```
DI
LD (IIMC2) ,XXXXXX0-B      ;  Change from “level” to “edge”.
LD (INTCLR), 0AH           ;  Clear interrupt request flag.
NOP                        ;  Wait EI execution.
NOP
NOP
EI
```

X: Don’t care, –: No change

Note 2: See electrical characteristics in section 4 for external interrupt input pulse width.

Note 3: In a setup of a port, when choosing a 16-bit timer input and performing capture control, INT5 and INT6 operate not according to a setup of IIMC2 and IIMC3 register but according to a setup of TB1MOD<TB1CPM1:0>.

Table 3.4.2 Settings of External Interrupt Pin Function

Interrupt Pin	Shared Pin	Mode	Setting Method
INT0	P74	 Rising edge	IIMC2<I0LE> = “0”, IIMC3<I0EDGE > = “0”
		 Falling edge	IIMC2<I0LE> = “0”, IIMC3<I0EDGE > = “1”

		 Falling edge	IIMC2<I7LE> = “0”, IIMC3<I7EDGE > = “1”
		 High level	IIMC2<I7LE> = “1”, IIMC3<I7EDGE > = “0”
		 Low level	IIMC2<I7LE> = “1”, IIMC3<I7EDGE > = “1”

(3) SIO receive interrupt control

Symbol	Name	Address	7	6	5	4	3	2	1	0
SIMC	SIO interrupt mode control	F5H (Prohibit RMW)	–					IR2LE	IR1LE	IR0LE
			W					W		
			0					1	1	1
			Always write "1" (Note)					0: INTRX2 edge mode 1: INTRX2 level mode	0: INTRX1 edge mode 1: INTRX1 level mode	0: INTRX0 edge mode 1: INTRX0 level mode

Note: When you use interruption, be sure to set "1" as the bit 7 of a SIMC register.

INTRX2 level enable

0	Edge detect INTRX2
1	"H" level INTRX2

INTRX1 level enable

0	Edge detect INTRX1
1	"H" level INTRX1

INTRX0 rising edge enable

0	Edge detect INTRX0
1	"H" level INTRX0

(4) Interrupt request flag clear register

The interrupt request flag is cleared by writing the appropriate micro DMA start vector, as given in Table 3.4.1, to the register INTCLR.

For example, to clear the interrupt flag INT0, perform the following register operation after execution of the DI instruction.

INTCLR ← 0AH Clears interrupt request flag INT0.

Symbol	Name	Address	7	6	5	4	3	2	1	0
INTCLR	Interrupt clear control	F8H (Prohibit RMW)	CLRV7	CLRV6	CLRV5	CLRV4	CLRV3	CLRV2	CLRV1	CLRV0
			W							
			0	0	0	0	0	0	0	0
			Interrupt vector							

(5) Micro DMA start vector registers

These registers assign micro DMA processing to sets which source corresponds to DMA. The interrupt source whose micro DMA start vector value matches the vector set in one of these registers is designated as the micro DMA start source.

When the micro DMA transfer counter value reaches "0", the micro DMA transfer end interrupt corresponding to the channel is sent to the interrupt controller, the micro DMA start vector register is cleared, and the micro DMA start source for the channel is cleared. Therefore, in order for micro DMA processing to continue, the micro DMA start vector register must be set again during processing of the micro DMA transfer end interrupt.

If the same vector is set in the micro DMA start vector registers of more than one channel, the lowest numbered channel takes priority.

Accordingly, if the same vector is set in the micro DMA start vector registers for two different channels, the interrupt generated on the lower numbered channel is executed until micro DMA transfer is complete. If the micro DMA start vector for this channel has not been set in the channel's micro DMA start vector register again, micro DMA transfer for the higher-numbered channel will be commenced. (This process is known as micro DMA chaining.)

Symbol	Name	Address	7	6	5	4	3	2	1	0
DMA0V	DMA0 start vector	100H			DMA0V5	DMA0V4	DMA0V3	DMA0V2	DMA0V1	DMA0V0
					R/W					
					0	0	0	0	0	0
					DMA0 start vector					
DMA1V	DMA1 start vector	101H			DMA1V5	DMA1V4	DMA1V3	DMA1V2	DMA1V1	DMA1V0
					R/W					
					0	0	0	0	0	0
					DMA1 start vector					
DMA2V	DMA2 start vector	102H			DMA2V5	DMA2V4	DMA2V3	DMA2V2	DMA2V1	DMA2V0
					R/W					
					0	0	0	0	0	0
					DMA2 start vector					
DMA3V	DMA3 start vector	103H			DMA3V5	DMA3V4	DMA3V3	DMA3V2	DMA3V1	DMA3V0
					R/W					
					0	0	0	0	0	0
					DMA3 start vector					
DMA4V	DMA4 start vector	104H			DMA4V5	DMA4V4	DMA4V3	DMA4V2	DMA4V1	DMA4V0
					R/W					
					0	0	0	0	0	0
					DMA4 start vector					
DMA5V	DMA5 start vector	105H			DMA5V5	DMA5V4	DMA5V3	DMA5V2	DMA5V1	DMA5V0
					R/W					
					0	0	0	0	0	0
					DMA5 start vector					
DMA6V	DMA6 start vector	106H			DMA6V5	DMA6V4	DMA6V3	DMA6V2	DMA6V1	DMA6V0
					R/W					
					0	0	0	0	0	0
					DMA6 start vector					
DMA7V	DMA7 start vector	107H			DMA7V5	DMA7V4	DMA7V3	DMA7V2	DMA7V1	DMA7V0
					R/W					
					0	0	0	0	0	0
					DMA7 start vector					

(6) Specification of a micro DMA burst

Specifying the micro DMA burst function causes micro DMA transfer, once started, to continue until the value in the transfer counter register reaches "0". Setting any of the bits in the register DMAB which correspond to a micro DMA channel (as shown below) to 1 specifies that any micro DMA transfer on that channel will be a burst transfer.

Symbol	Name	Address	7	6	5	4	3	2	1	0
DMAB	DMA burst	108H	DBST7	DBST6	DBST5	DBST4	DBST3	DBST2	DBST1	DBST0
			R/W							
			0	0	0	0	0	0	0	0
			1: DMA burst request							

(7) Notes

The instruction execution unit and the bus interface unit in this CPU operate independently. Therefore, immediately before an interrupt is generated, if the CPU fetches an instruction which clears the corresponding interrupt request flag, the CPU may execute this instruction in between accepting the interrupt and reading the interrupt vector. In this case, the CPU will read the default vector 0004H and jump to interrupt vector address FFFF04H.

To avoid this, an instruction which clears an interrupt request flag should always be placed after a DI instruction. And in the case of setting an interrupt enable again by EI instruction after the execution of clearing instruction, execute EI instruction after clearing and more than 3–instructions (e.g., "NOP" × 3 times).

If it placed EI instruction without waiting NOP instruction after execution of clearing instruction, interrupt will be enabled before request flag is cleared.

In the case of changing the value of the interrupt mask register <IFF2:0> by execution of POP SR instruction, disable an interrupt by DI instruction before execution of POP SR instruction.

In addition, please note that the following two circuits are exceptional and demand special attention.

INT0 to INT7 level mode	In level mode INT0 is not an edge triggered interrupt. Hence, in level mode the interrupt request flip-flop for INT0 does not function. The peripheral interrupt request passes through the S input of the flip-flop and becomes the Q output. If the interrupt input mode is changed from edge mode to level mode, the interrupt request flag is cleared automatically.

	If the CPU enters the interrupt response sequence as a result of INT0 going from "0" to "1", INT0 must then be held at "1" until the interrupt response sequence has been completed. If INT0 to INT7 are set to level mode so as to release a halt state, INT0 must be held at "1" from the time INT0 changes from "0" to "1" until the halt state is released. (Hence, it is necessary to ensure that input noise is not interpreted as a "0", causing INT0 to revert to "0" before the halt state has been released.)
	When the mode changes from level mode to edge mode, interrupt request flags which were set in level mode will not be cleared. Interrupt request flags must be cleared using the following sequence.
	DI
	LD (IIMC2), 00H ; Switches from level to edge.
	LD (INTCLR), 0AH ; Clears interrupt request flag.
	NOP ; Wait EI execution
	NOP
	NOP
	EI

INTRX0 to INTRX2	In level mode (the register SIMC<IRxLE> set to "0"), the interrupt request flip-flop can only be cleared by a reset or by reading the serial channel receive buffer. It cannot be cleared by writing INTCLR register.

Note: The following instructions or pin input state changes are equivalent to instructions which clear the interrupt request flag.

INT0 to INT7: Instructions which switch to level mode after an interrupt request has been generated in edge mode.

The pin input changes from "high to low" and "low to high" after an interrupt request has been generated in level mode. ("H" → "L", "L" → "H")

INTRX0 to INTRX2: Instructions which read the receive buffer.

3.5 Function of Ports

The TMP92CY23/CD23A I/O port pins are shown in Table 3.5.1. In addition to functioning as general-purpose I/O ports, these pins are also used by the internal CPU and I/O functions. Table 3.5.2 to Table 3.5.4 list the I/O registers and their specifications.

Table 3.5.1 Port Functions

(R: PU = with programmable pull-up resistor, U = with pull-up resistor)

Port Name	Pin Name	Number of Pins	I/O	R	I/O Setting	Pin Name for Built-in Function
Port 0	P00 to P07	8	I/O	–	Bit	D0 to D7
Port 1	P10 to P17	8	I/O	–	Bit	D8 to D15

3.5.1 Port 0 (P00 to P07)

Port 0 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P0CR and function register P0FC.

In addition to functioning as a general-purpose I/O port, port 0 can also function as a data bus (D0 to D7).

Moreover, after reset release, since a device is set as an input port, when using it as a data bus (D0 to D7), it needs to set it as P0CR and P0FC.

Note2: <P0xC> is bit x of P0CR register.

Figure 3.5.2 Register for Port 0

3.5.2 Port 1 (P10 to P17)

Port 1 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P1CR and function register P1FC.

In addition to functioning as a general-purpose I/O port, port1 can also function as a data bus (D8 to D15).

Moreover, after reset release, since a device is set as an input port, when using it as a data bus (D8 to D15), it needs to set it as P1CR and P1FC.

Note2: <P1xC> is bit x of P1CR register.

Figure 3.5.4 Register for Port 1

3.5.3 Port 4 (P40 to P47)

Port4 is 8-bit general-purpose I/O ports. Bits can be individually set as either inputs or outputs by control register P4CR and function register P4FC. In addition to functioning as a general-purpose I/O port, port4 can also function as an address bus (A0 to A7).

Moreover, after reset release, since a device is set as an input port, when using it as an address bus (A0 to A7), it needs to set it as P4CR and P4FC.

Note2: When using as address bus A0 to A7, set P4FC after set P4CR.

Figure 3.5.6 Register for Port 4

3.5.4 Port 5 (P40 to P47)

Port5 is 8-bit general-purpose I/O ports. Bits can be individually set as either inputs or outputs by control register P5CR and function register P5FC. In addition to functioning as a general-purpose I/O port, port 5 can also function as an address bus (A8 to A15).

Moreover, after reset release, since a device is set as an input port, when using it as an address bus (A8 to A15), it needs to set it as P5CR and P5FC.

Figure 3.5.8 Register for Port 5

3.5.5 Port 6 (P60 to P67)

Port 6 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P6CR and function register P6FC.

In addition to functioning as a general-purpose I/O port, port 6 can also function as an address bus (A16 to A23).

Moreover, after reset release, since a device is set as an input port, when using it as a address bus (A16 to A23), it needs to set it as P6CR and P6FC.

Note2: When using as address bus A16 to A23, set P6FC after set P6CR.

Figure 3.5.10 Register for Port 6

3.5.6 Port 7 (P70 to P74, P76, P77)

As for a port7, P70 to P73, and P76 and P77 are general-purpose I/O ports, and P74 is a port only for inputs.

P76 and P77 become an open drain output, when it is set as an output port. Moreover, P70 to P73 are ports with pull-up resistance. Bits can be individually set as either inputs or outputs by control register P7CR and function register P7FC.

In addition to functioning as a general-purpose I/O port, port7 can also function as a CPU's control. P70 to P73 has the function of RD strobe signal output as an object for external memory connection, and the output for SRAM control ($\overline{SRWR}$, $\overline{SRLLB}$ and $\overline{SRLUB}$). P74 has the function of an external interrupt input (INT0). P76 and P77 have the function of a low-frequency resonator connection (XT1, XT2). These setups become effective by setting "1" as the applicable bit of P7CR and a P7FC register. The edge of the external interruption INT0 and level selection are set up in IIMC2 and IIMC3 registers in an interruption controller. P70 to P74 become input mode by the reset action, and P76 and P77 become output mode (high impedance output).

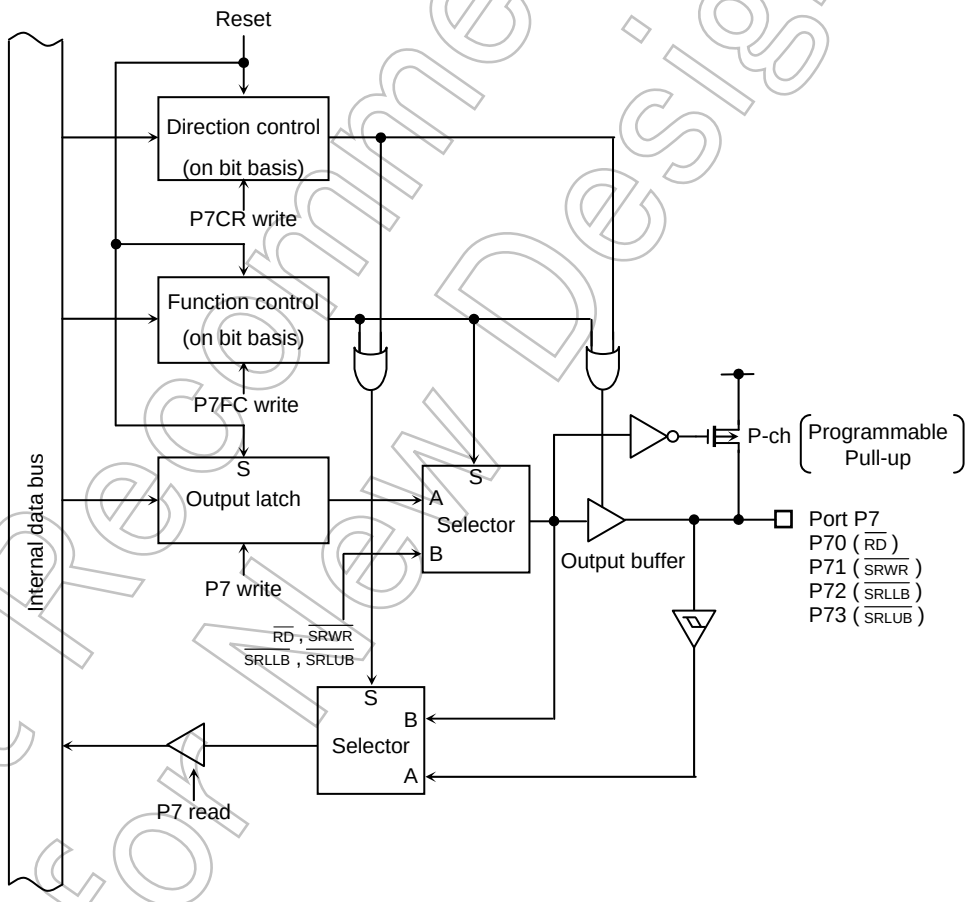

Figure 3.5.11 Port 7 (P70 to P73)

Port 7 Function register

P7FC (001FH)

	7	6	5	4	3	2	1	0
Bit symbol				P74F	P73F	P72F	P71F	P70F
Read/Write				W				
Reset State				0	0	0	0	0
Function				0: Port 1: INT0	0: Port 1: $\overline{\text{SRLUB}}$	0: Port 1: $\overline{\text{SRLLB}}$	0: Port 1: $\overline{\text{SRWR}}$	0: Port 1: $\overline{\text{RD}}$

Note 1: When port P70 to P73 is used in the input mode, P7 register controls the built-in pull-up resistor. Read-modify-write is prohibited in the input mode or the I/O mode. Setting the built-in pull-up resistor may be depended on the states of the input pin.

Note 2: A read-modify-write operation cannot be performed in P7CR and P7FC registers.

Note 3: On using low-frequency resonator to P76, P77, it is necessary to set the following procedures to reduce the consumption power supply.

・connecting to a resonator

P7CR <P76C,P77C> = "11", P7 <P76,P77> = "00"

・connecting an oscillator

P7CR <P76C,P77C> = "11", P7 <P76,P77> = "10"

Figure 3.5.14 Register for Port 7

3.5.7 Port 8 (P80 to P83)

Ports 80 to 82 are 3-bit output ports, and Port 83 is 1-bit I/O port.

In addition to an output and an I/O port function, as for P80 and P81, a standard chip select signal output ($\overline{CS0}$, $\overline{CS1}$) and a 8-bit timer output (TA1OUT, TA3OUT), and P82 have a standard chip select signal output ($\overline{CS2}$), and P83 has the function of a standard chip select signal output ($\overline{CS3}$), a 8-bit timer output (TA5OUT), and a wait input ($\overline{WAIT}$).

These functions operate by setting the bit concerned of P8CR, P8FC, and P8FC2 register as "1". All bits of P8FC and P8FC2 are cleared to "0" by the reset action, and P80 to P83 becomes an output port. Moreover, the output latch of P82 is cleared to "0" and the output latch of P80 to P81 and P83 is set to "1".

(1) P80 ($\overline{CS0}$, TA1OUT), P81 ($\overline{CS1}$, TA3OUT)

In addition to an output port function, ports P80 and P81 function as a standard chip select signal output ($\overline{CS0}$, $\overline{CS1}$) and a 8-bit timer output (TA1OUT, TA3OUT).

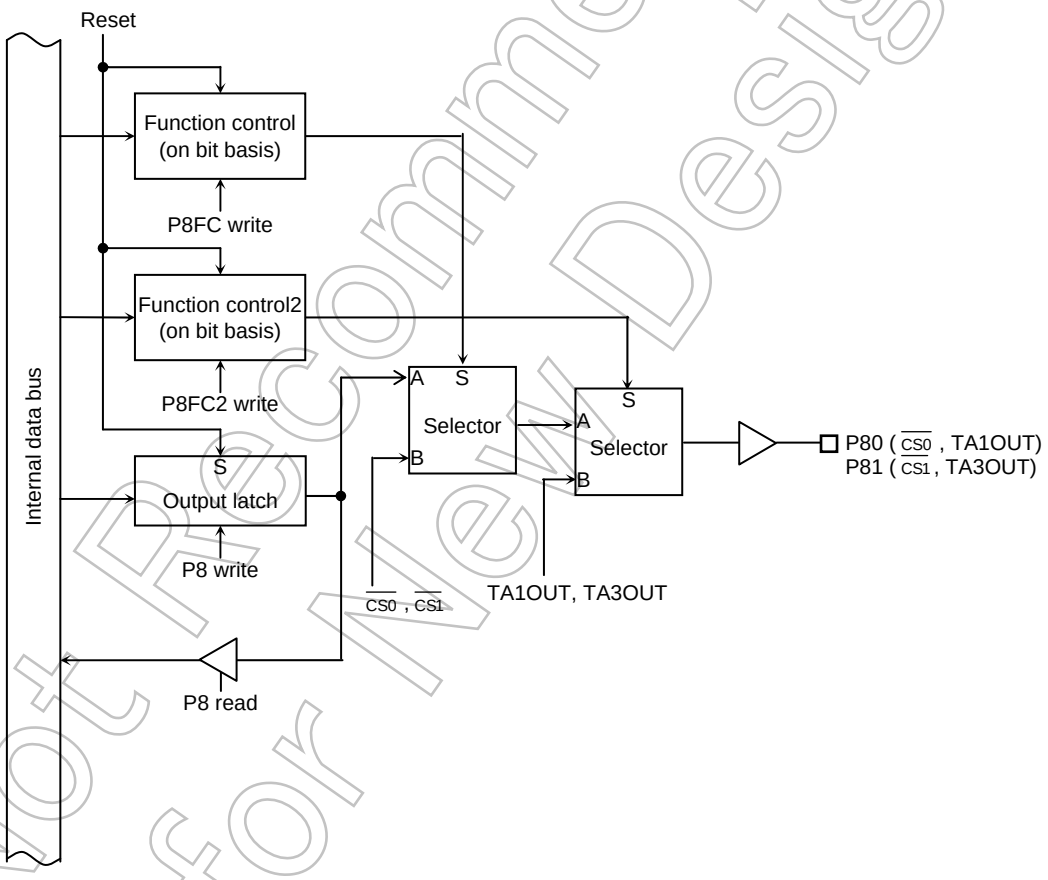

Figure 3.5.15 Port 8 (P80, P81)

(2) P82 ($\overline{CS2}$)

In addition to an output port function, a port P82 functions as a standard chip select signal output ($\overline{CS2}$).

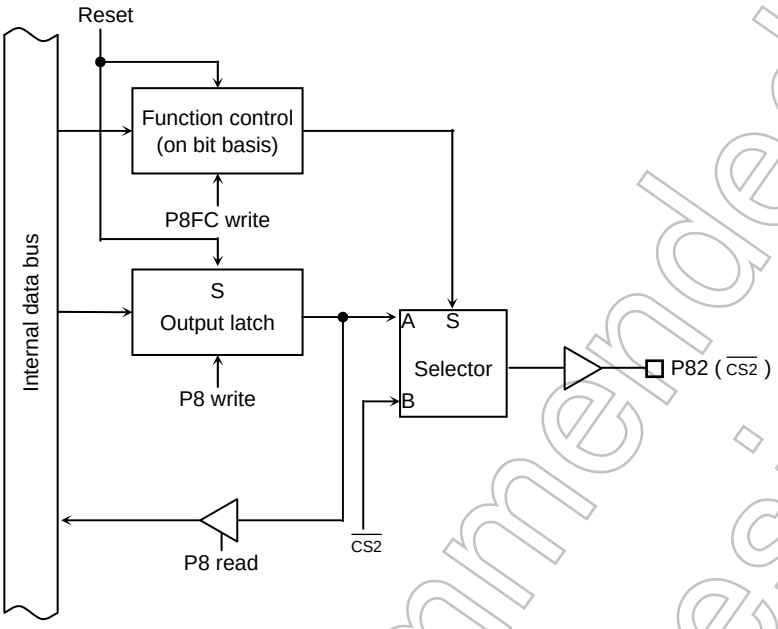

Figure 3.5.16 Port 8 (P82)

(3) P83($\overline{CS3}$, $\overline{WAIT}$, TA5OUT)

In addition to an I/O port function, a port P83 functions as a standard chip select signal output ($\overline{CS3}$) and an 8-bit timer output (TA5OUT), and a wait input ($\overline{WAIT}$).

<P83F:P83F2>		<P83C> 0	<P83C> 1
0	0	Input port	Output port
0	1	Reserved	TA5OUT
1	0	$\overline{WAIT}$	$\overline{CS3}$
1	1	Reserved	Reserved

Note 1: Output latch register is set to "1".

Note 2: A read-modify-write operation cannot be performed in P8CR, P8FC and P8FC2 registers.

Note 3: When using P83 as a $\overline{WAIT}$ input, while setting it as P8CR <P83C> = "0", P8FC<P83F> = "1", it is necessary to set memory control register BxCSL <BxWW2:0> or <BxWR2:0> as "011".

Note 4: When setting a standard chip select signal ($\overline{CS0}$ to $\overline{CS3}$) as an output, P8CR is set up after setting up P8FC.

Figure 3.5.18 Register for Port 8

3.5.8 Port C (PC0 to PC3)

Port C is a 4-bit input port.

In addition to the input port function, Port C has the input function (TA0IN) of a 8-bit timer, and an external interrupt input function (INT1 to INT3). These functions operate by setting the bit concerned of PCFC register as "1". Edge selection of external interrupt is set up in IIMC2 and IIMC3 register in an interrupt controller. All bits of PCFC are cleared to "0" by the reset action, and all bits serve as an input port.

(1) PC0 (TA0IN)

In addition to an I/O port function, a port PC0 has a function as a TA0IN input of the timer channel 0.

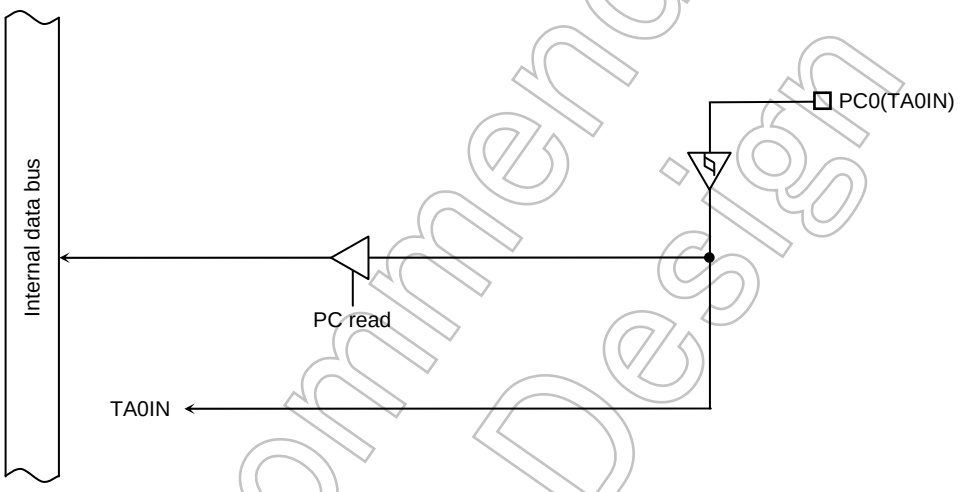

Figure 3.5.19 Port C (PC0)

(2) PC1 (INT1), PC2 (INT2), PC3 (INT3)

In addition to an Input port function, port PC1 to PC3 has a function as an external interrupt input (INT1 to INT3).

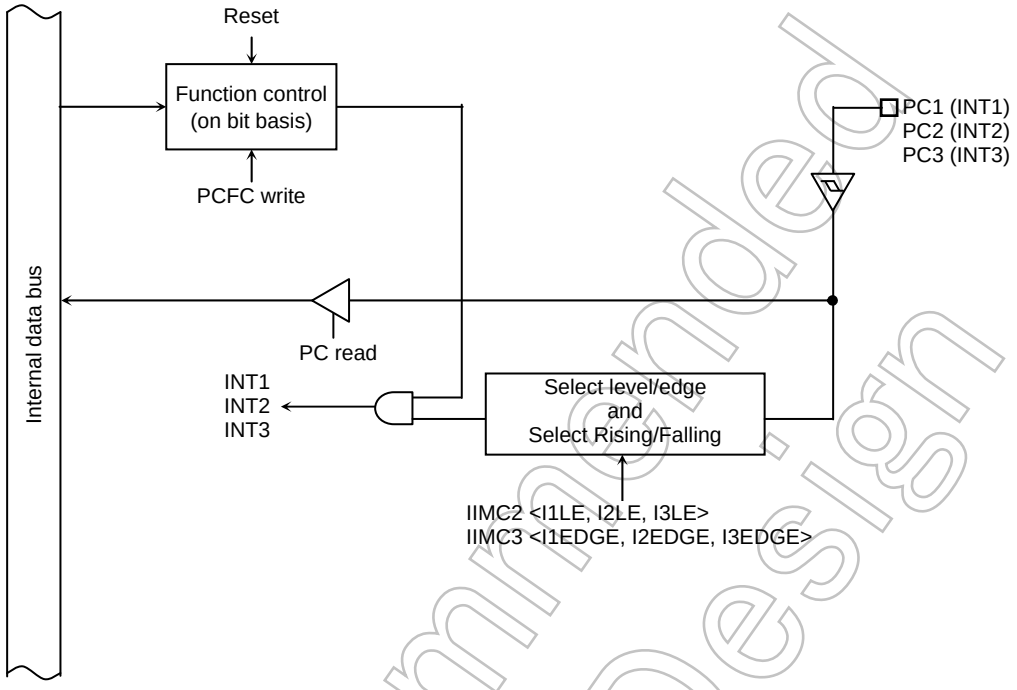

Figure 3.5.20 Port C (PC1, PC2 and PC3)

Port C Register

		7	6	5	4	3	2	1	0

	Reset State					0	0	0	0
	Function					0: Port 1: INT3	0: Port 1: INT2	0: Port 1: INT1	0: Port 1: TA0IN

Note1: A read-modify-write operation cannot be performed in PCFC register.

Note2: PC0 is not based on a functional setup of a port, but is inputted into TA0IN of a 8-bit timer (TMRA0).

Figure 3.5.21 Register for Port C

3.5.9 Port D (PD0 to PD4)

Port D is 4-bit I/O port (PD0, PD2 to PD4) and 1-bit input port (PD1).

There are I/O of the serial channel 2, I/O of a 16-bit timer (TMRB0, TMRB1), and an external interrupt input (INT4 to INT7) function in addition to an I/O port function. These functions operate by setting the bit concerned of PDCR, PDFC and PDFC2 register as "1". Edge selection of external interrupt is set up in IIMC2 and IIMC3 register in an interrupt controller. All bits of PDCR, PDFC and PDFC2 are cleared to "0" by the reset action, and all bits serve as an input port.

(1) PD0 (INT4, TB0OUT0)

In addition to an I/O port function, a port PD0 has a function as a 16-bit timer output (TB0OUT0) and an external interrupt input (INT4).

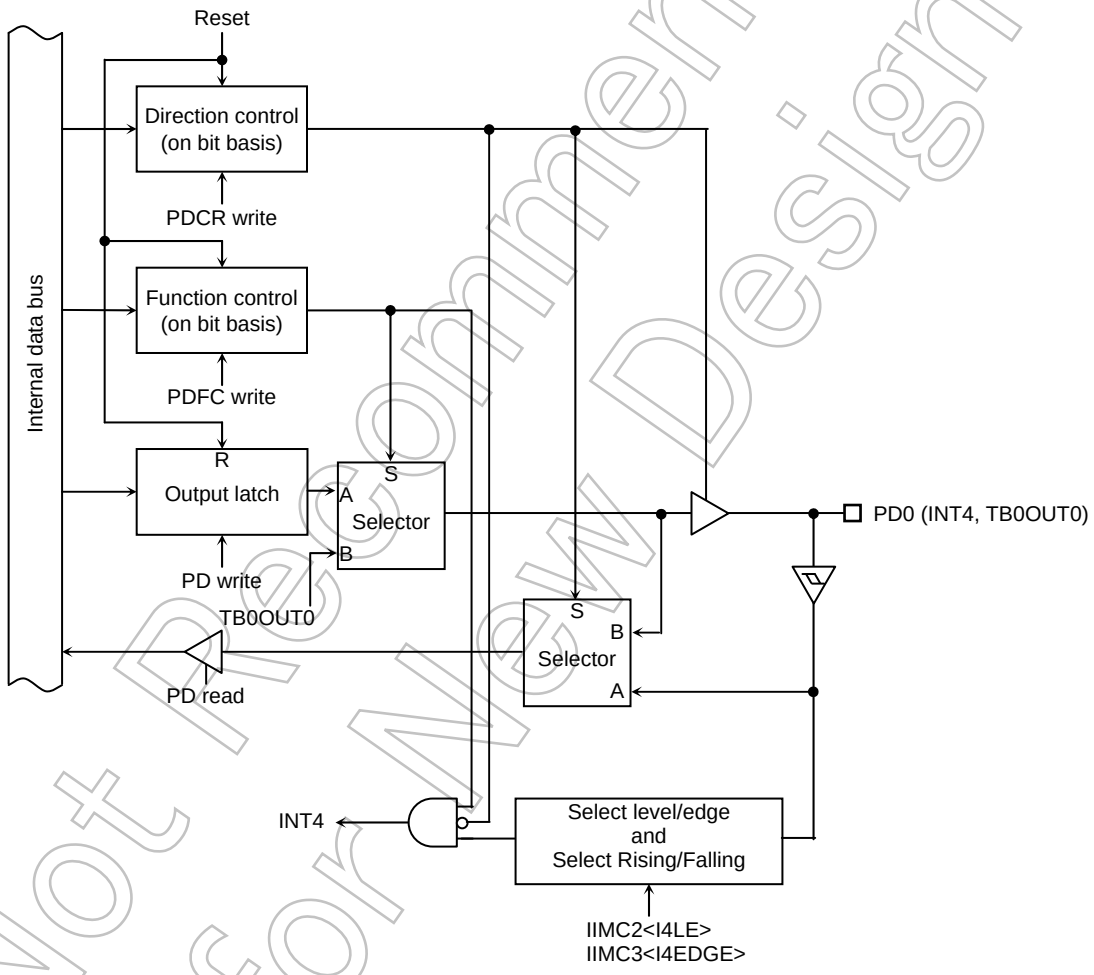

Figure 3.5.22 Register for Port D (PD0)

(2) PD1 (INT5,TB1IN0)

In addition to the input port function, the port PD1 has a function as a 16-bit timer input (TB1IN0) and an external interrupt input (INT5). In a port setup, when choosing a 16-bit timer input and performing capture control, INT5 disregards a setup of IIMC2 and IIMC3 registers, and operates according to a setup of TB1MOD <TB1CPM1:0>.

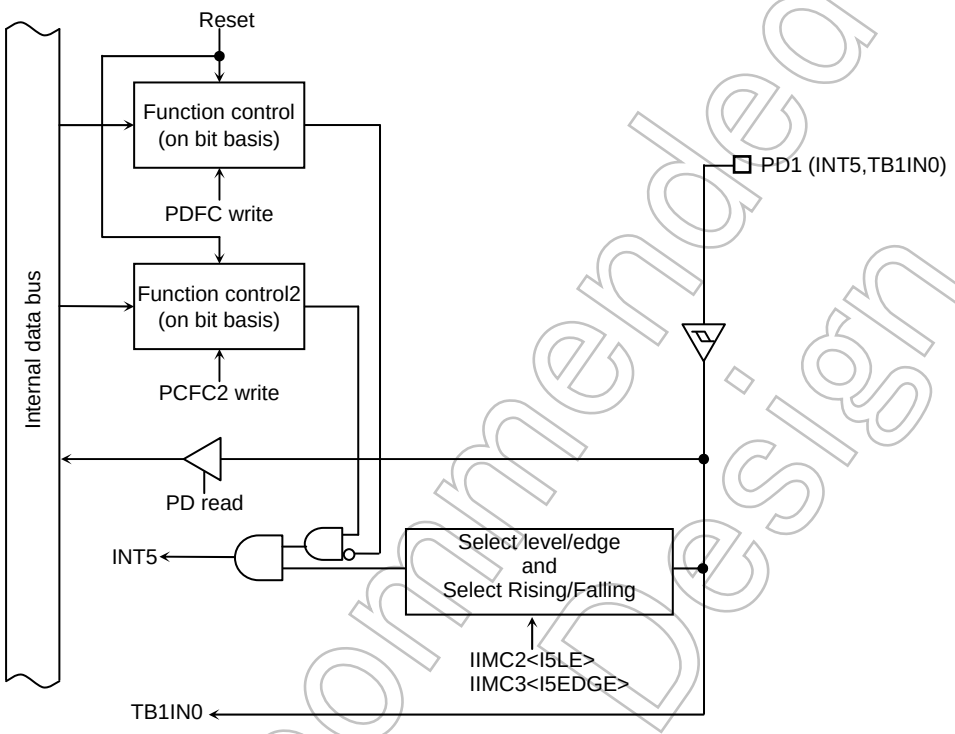

Figure 3.5.23 Port D (PD1)

(3) PD2 (INT6, TB1IN1, TXD2)

In addition to the I/O port, PD2 has a function as a 16-bit timer input (TB1IN1), an external interrupt input (INT6), and a TXD output (TXD2) of the serial channel 2. When using this port as TXD output (TXD2), it can be set as open drain.

In a port setup, when choosing a 16-bit timer input and performing capture control, INT6 disregards a setup of IIMC2 and IIMC3 registers, and operates according to a setup of TB1MOD <TB1CPM1:0>.

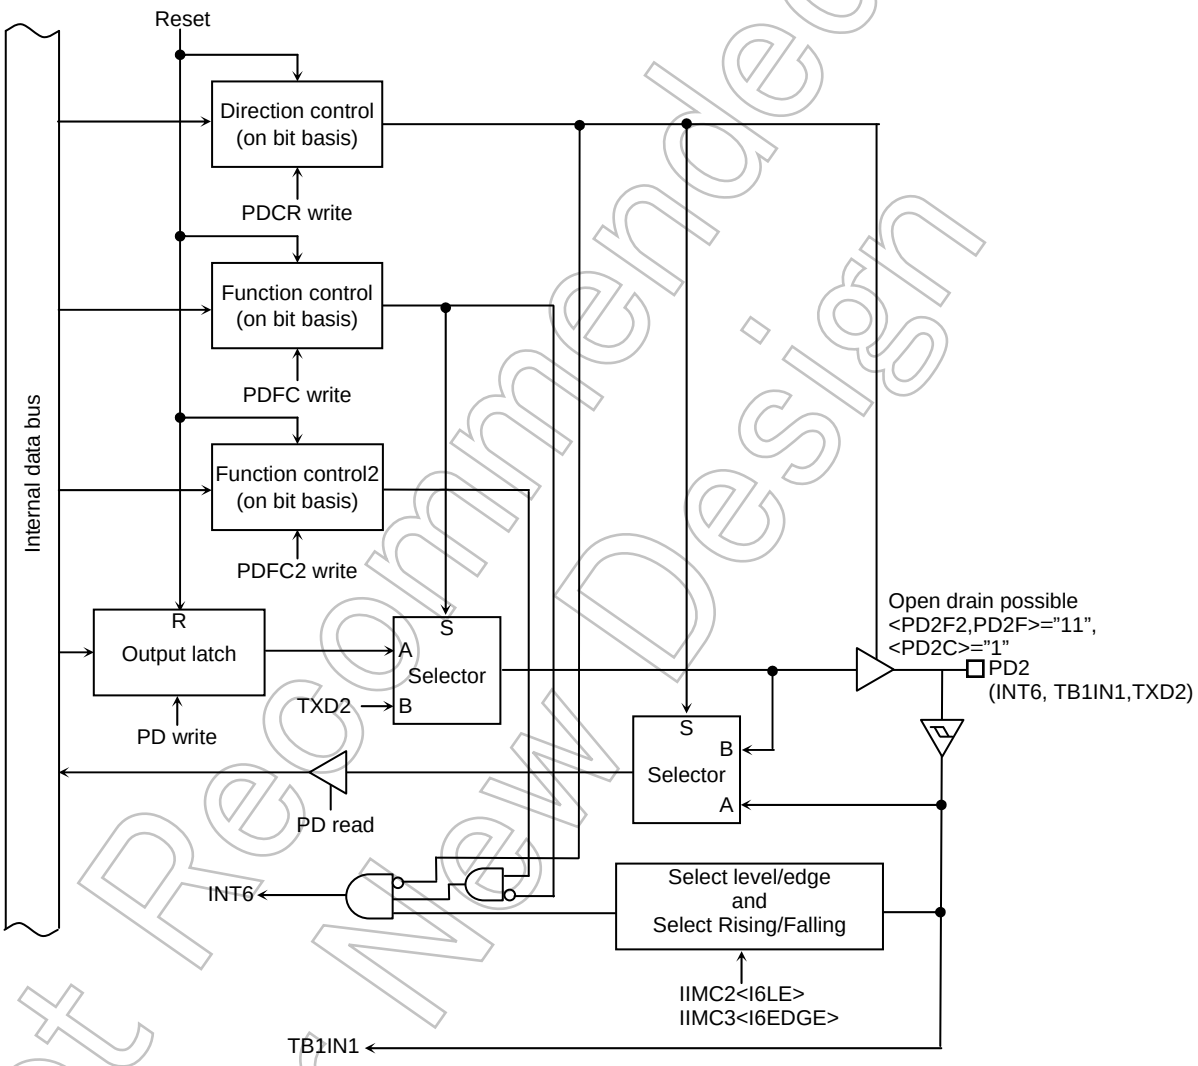

Figure 3.5.24 Port D (PD2)

(4) PD3 (INT7, TB1OUT0, RXD2)

In addition to the I/O port function, the portD3 has a function as a 16-bit timer output (TB1OUT0), an external interrupt input (INT7), and a RXD input (RXD2) of the serial channel 2.

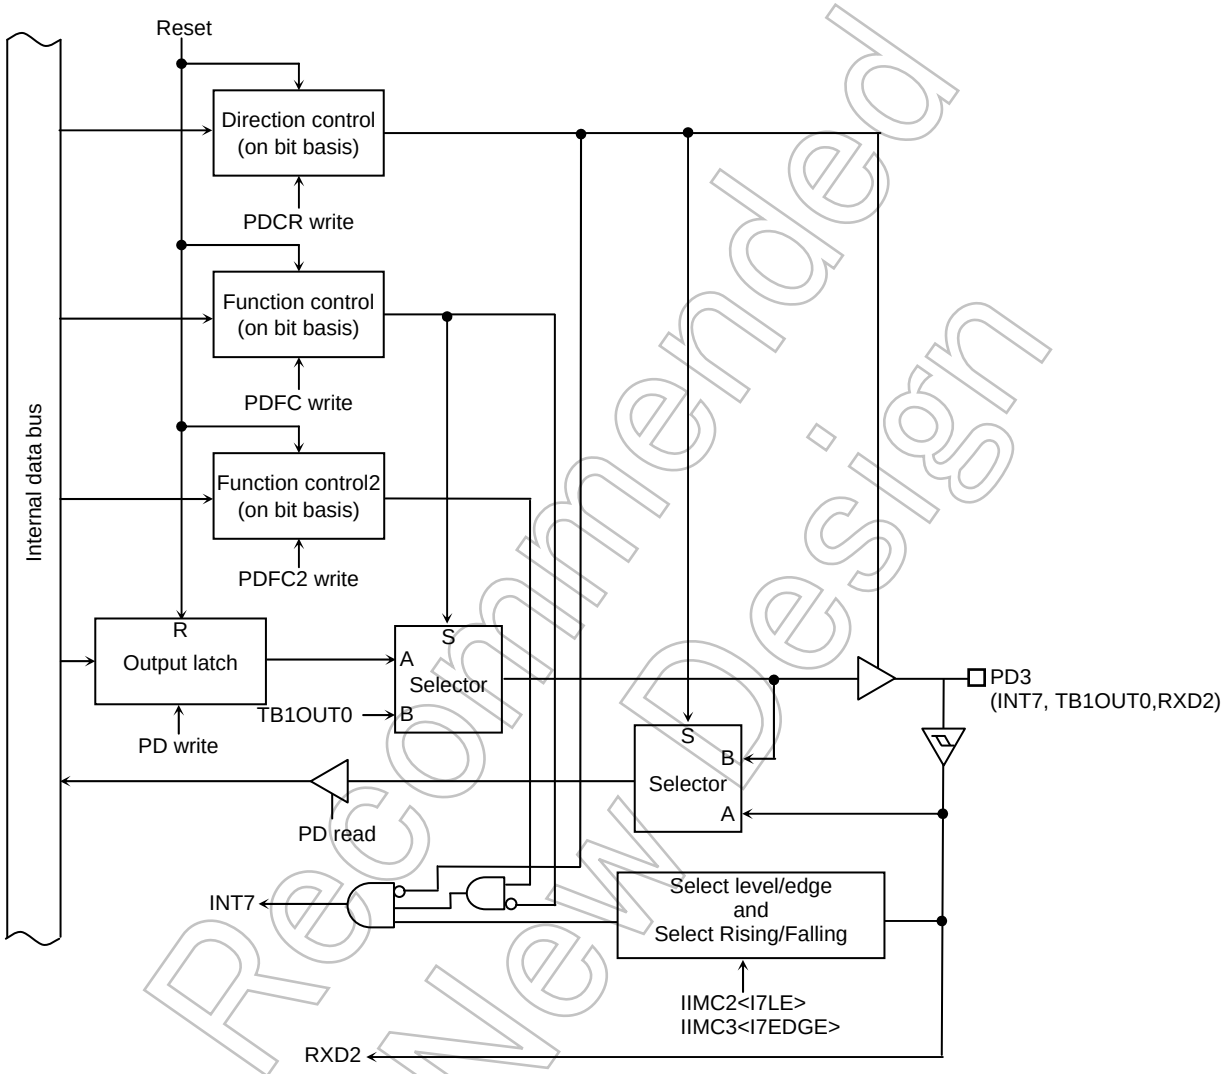

Figure 3.5.25 Port D (PD3)

(5) PD4 (TB1OUT1, SCLK2, $\overline{CTS2}$)

In addition to the I/O port function, PD4 has a function as a 16-bit timer output (TB1OUT1), SCLK I/O (SCLK2) of the serial channel 2, or a CTS input ($\overline{CTS2}$).

PD4 to PD0 function setting

<PDxF2, PDxF, PDxC>	PD4	PD3	PD2	PD1 (Note 3)	PD0 (Note 4)
0 , 0 , 0	Input port	Input port	Input port	Input port	Input port
0 , 0 , 1	Output port	Output port	Output port		Output port
0 , 1 , 0	Reserved	RXD2	TB1IN1	TB1IN0	INT4
0 , 1 , 1	TB1OUT1	TB1OUT0	TXD2(3-state)		TB0OUT0
1 , 0 , 0	SCLK2, $\overline{CTS2}$ input	INT7	INT6	INT5	
1 , 0 , 1	SCLK2 output	Reserved	Reserved		
1 , 1 , 0	Reserved	Reserved	Reserved	Reserved	
1 , 1 , 1	Reserved	Reserved	TXD2(O.D)		

Note : <PDxF2>,<PDxF> and <PDxC> are the bits x of PDFC2,PDFC and PDCR registers.

Note 1: Output latch register is cleared to “0”.

Note 2: There is no output latch register in PD1.

Note 3: A read-modify-write operation cannot be performed in PDCR, PDFC and PDFC2 registers.

Note 4: TB1IN0 and TB1IN1 input is inputted into the 16-bit timer TMRB1 irrespective of a functional setup of a port.

Note 5: RXD2, SCLK2 input, and $\overline{CTS2}$ input are inputted into the serial channel 2 irrespective of a functional setup of a port.

Note 6: PD2 does not have a register for 3-state/open drain setup. Moreover, there is no open drain function at the time of an output port.

Figure 3.5.27 Register for Port D

3.5.10 Port F (PF0 to PF5)

Port F is a 6-bit general-purpose I/O ports.

All bits of PFCR, PFFC and PFFC2 are cleared to "0" by the reset action, and all bits serve as an input port.

In addition to an I/O port, there are I/O of the serial channels 0 and 1, high speed serial channel(Note) and an internal clock output function. These functions operate by setting the bit concerned of PFCR, PFFC, PFFC2, HSCSEL register as "1". All bits of PFCR, PFFC, PFFC2 and HSCSEL are cleared to "0" by the reset action, and all bits serve as an input port.

Note: The high speed serial channel function is not built into TMP92CY23.

(1) Port F0 (TXD0)

In addition to an I/O port function, PF0 have a function as an output (TXD0) of the serial channels 0.

Moreover, when using it as a TXD output terminal, the output buffer has the open drain function in which a program is possible. An open drain function can be set up by the PFFC <PF0F>, PFCR <PF0C> register.

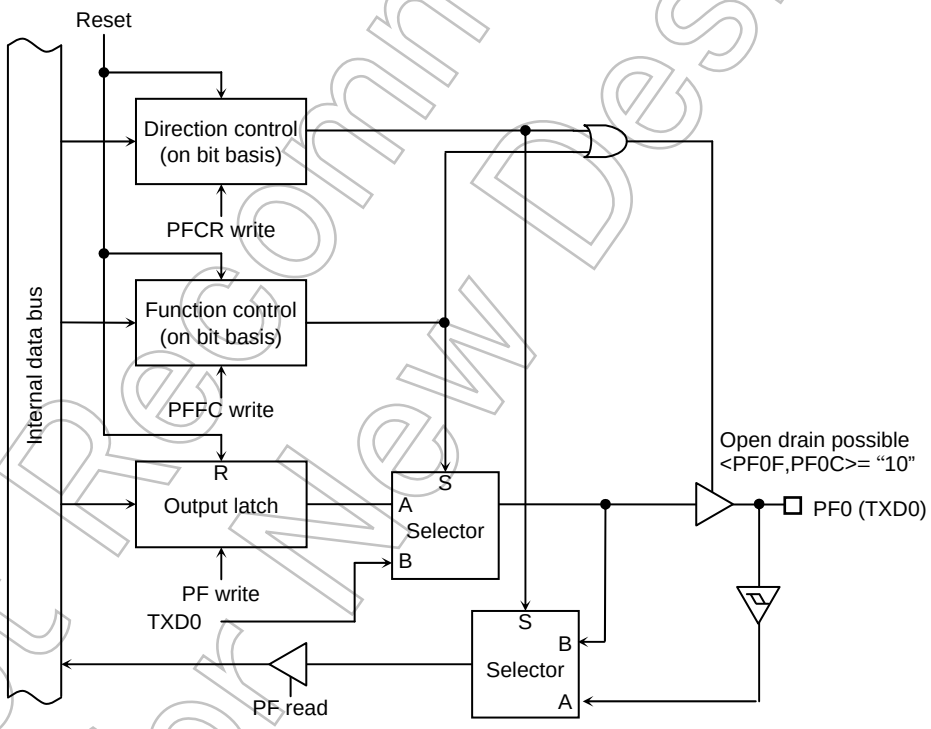

Figure 3.5.28 Port F (PF0)

(2) PF1(RXD0)

In addition to the I/O port, PF1 have a function as an input (RXD0) of the serial channels 0.

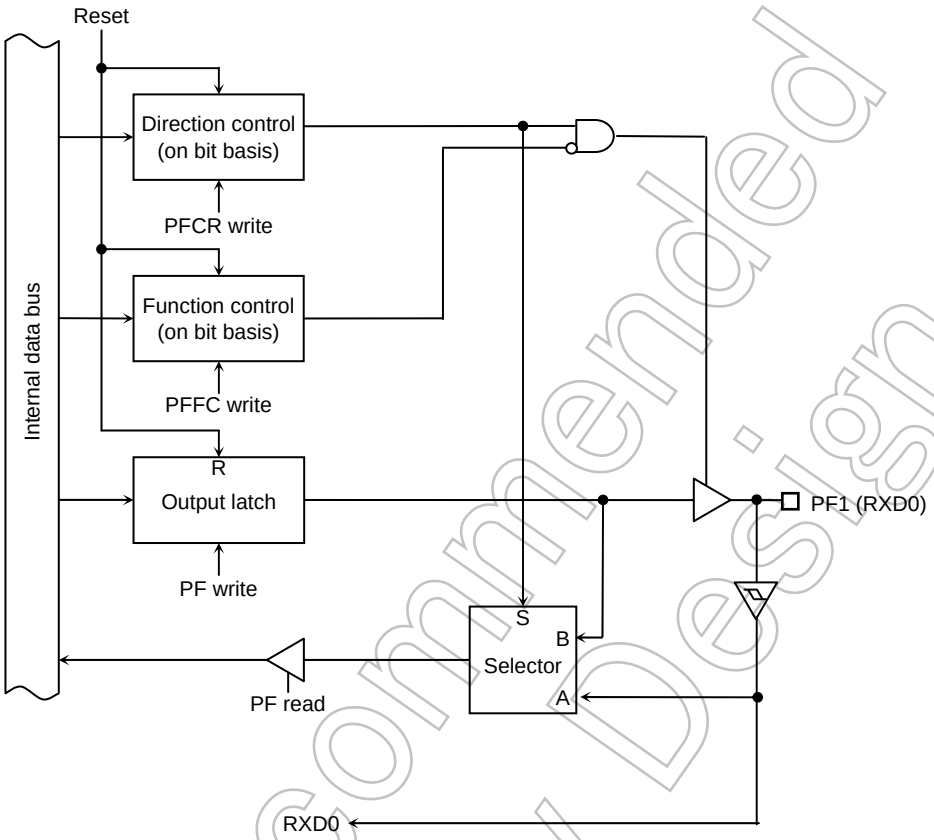

Figure 3.5.29 Port F (PF1)

(3) PF2 ($\overline{CTS0}$, SCLK0, CLK)

In addition to the I/O port, PF2 has a function as the CTS input ($\overline{CTS0}$), SCLK I/O (SCLK0), and the internal clock output (CLK) of the serial channel 0.

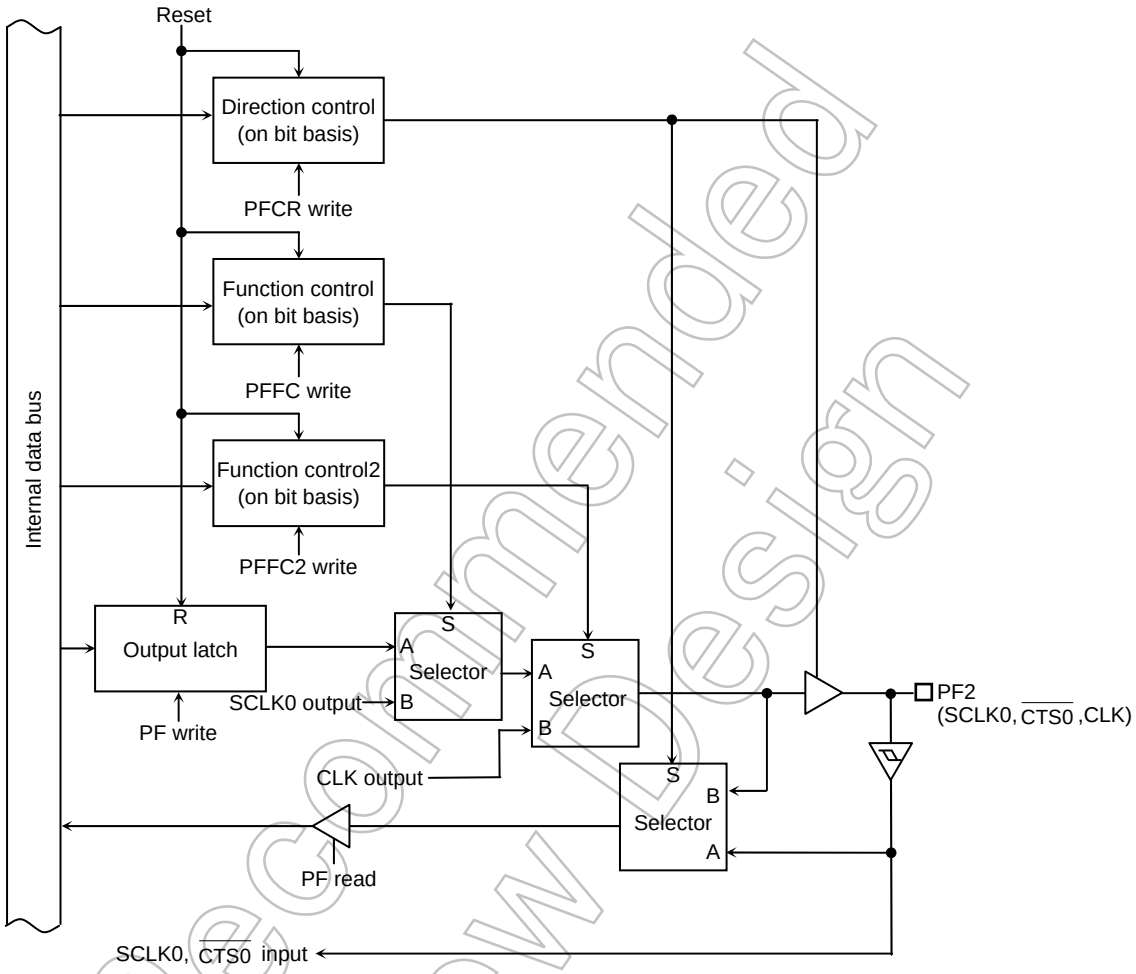

Figure 3.5.30 Port F (PF2)

(4) Port F3 (TXD1, HSSO)

In addition to an I/O port function, PF3 have a function as an output (TXD1) of the serial channels 1 and output (HSSO) of the high speed serial channels (Note).

Moreover, when using it as a TXD output terminal, the output buffer has the open drain function in which a program is possible. An open drain function can be set up by the PFFC <PF3F>, PFCR <PF3C> register.

Note: HSSO output function is not built into TMP92CY23.

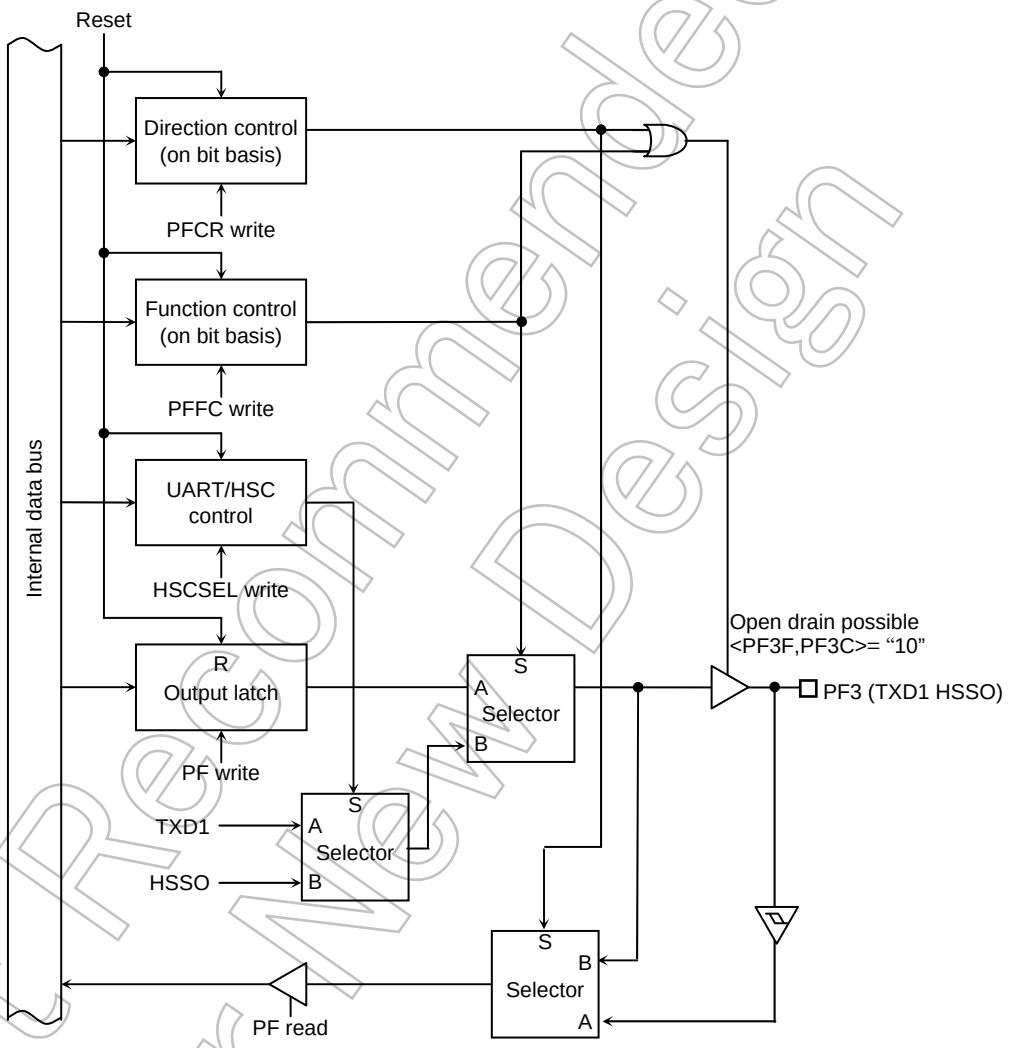

Figure 3.5.31 Port F (PF3)

(5) PF4(RXD1, HSSI)

In addition to the I/O port, PF4 have a function as an input (RXD1) of the serial channels 0 and input (HSSI) of high speed serial channels(Note).

Note: HSSI input function is not built into TMP92CY23.

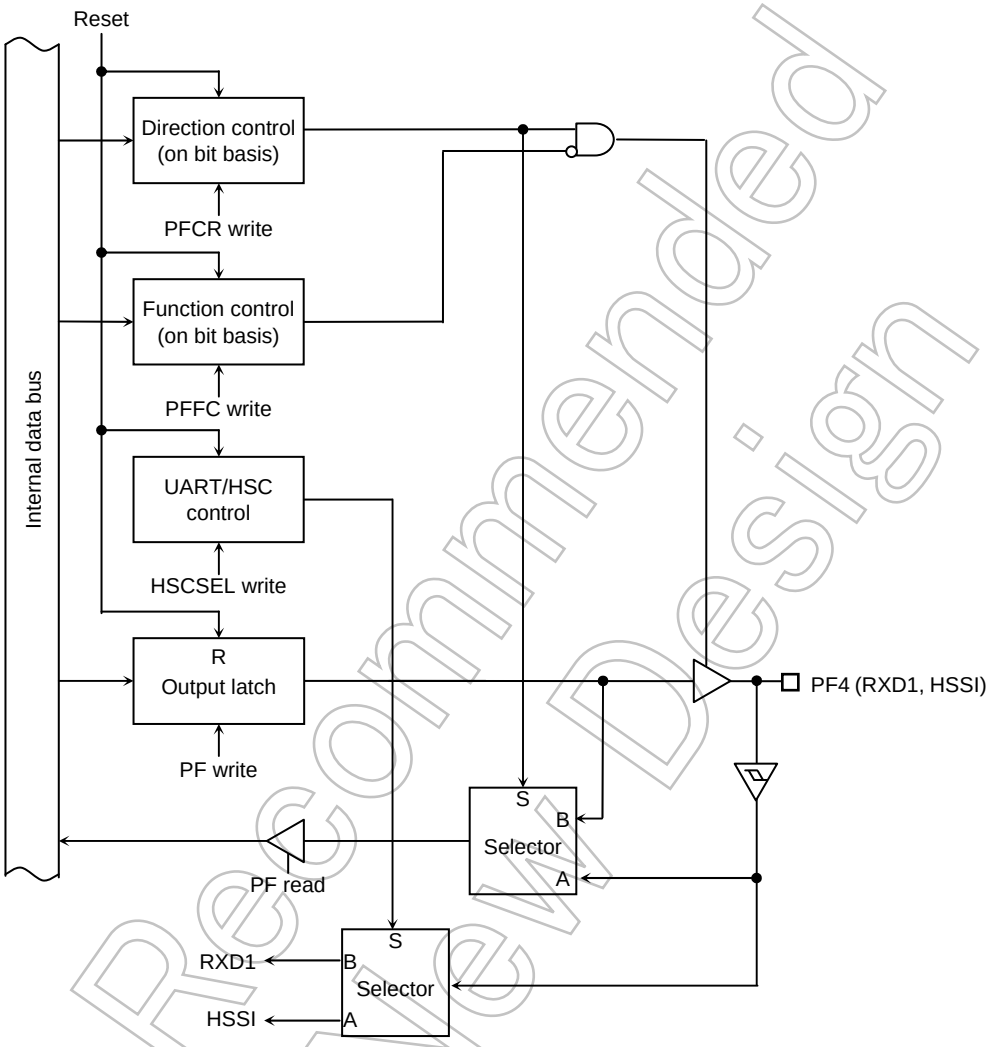

Figure 3.5.32 Port F (PF4)

(6) PF5 ($\overline{CTS1}$, SCLK1, HSCLK)

In addition to the I/O port function, PF5 has a function as the input ($\overline{CTS1}$) or I/O (SCLK1) of the serial channel 1 and output (HSCLK) of high speed serial channels(Note).

Note: HSCLK output function is not built into TMP92CY23.

Note 1: A read-modify-write operation cannot be performed in PDCR, PDFC and PDFC2 registers.

Note 2: PF0 and PF3 does not have a register for 3-state/open drain setup. Moreover, there is no open drain function at the time of an output port.

Note3: HSSO,HSSI and HSCLK functions are not built into TMP92CY23.

Figure 3.5.34 Register for Port F

3.5.11 Port G (PG0 to PG7)

Port G is 8-bit general-purpose input ports. In addition to an input port function, there are an analog input for AD converters (AN0 to AN7) and a key input (KI0 to KI7) function for a Key on wake up. These functions operate by setting the bit concerned of PGFC, KIEN register as "1". Moreover, edge selection of a key input is set up by the KICR register.

By the reset action, all bits of PGFC are set to “1”, and all bits of KIEN are cleared to “0”, and it becomes all bit analog input ports (port input disable).

A key input is enabled by the KIEN register, and when the edge chosen in the KICR register is detected, the Key on wake up input KWI occurs. Although a Key on wake up input can release all HALT mode states, there is no function as interrupt.

Note : <PGxF> and <KIxEN> are the bits x of PGFC and KIEN registers.

Note 1: It operates as an analog input port (Input port disable).

Note 2: A read-modify-write operation cannot be performed in PGFC,KIEN and KICR registers.

Note 3: The input channel selection of the AD conberter is set by AD mode control register ADMOD1.

Figure 3.5.36 Register for Port G

3.5.12 Port L (PL0 to PL3)

Port L is a 4-bit input port. In addition to an input port function, Port L has the analog input function of an AD converter. Moreover, PL3 has the $\overline{\text{ADTRG}}$ function of an AD converter. When you use PL3 as an $\overline{\text{ADTRG}}$, set PLFC <PL3F> as "0". All bits of a PLFC register are set to "1" by the reset action, and Port L become analog input port (port input disable).

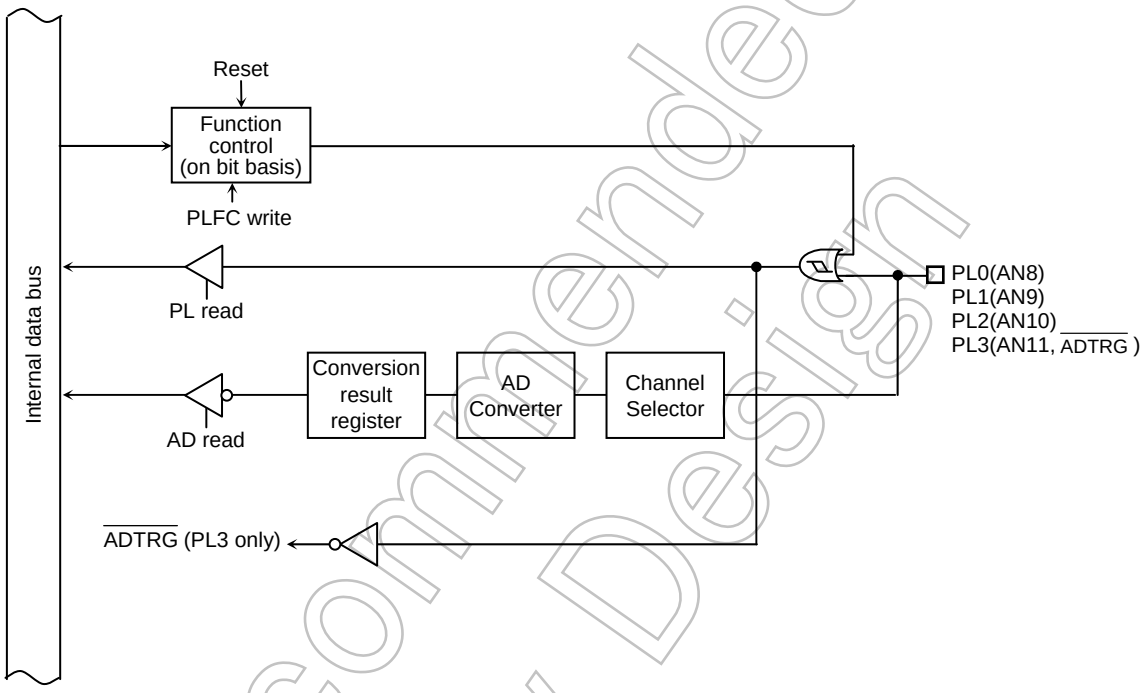

Figure 3.5.37 Port L

	Read/Write					W			
	Reset State					1	1	1	1
	Function					0: Analog input 1:Input port (Note3)			

Note 1: It operates as an analog input port (Input port disable).

Note 2: A read-modify-write operation cannot be performed in PLFC register.

Note 3: The input channel selectino of the AD converter is set by AD mode control register ADMOD1<ADCH3:0>. Moreover, a set up of AD trigger ($\overline{\text{ADTRG}}$) input permission is set by ADMOD2<ADTRGE>.

Figure 3.5.38 Register for Port L

3.5.13 Port N (PN0 to PN5)

Port N is 6-bit general-purpose I/O ports. Moreover, PN1, PN2, PN4, and PN5 serve as an open drain output, when it is set as an output.

There are the following functions in addition to an I/O port.

・The I/O function of the serial bus interface 0 (SCK0, SO0/SDA0, SI0/SCL0)

・The I/O function of the serial bus interface 1 (SCK1, SO1/SDA1, SI1/SCL1)

These functions operate by setting the bit concerned of PNCR, PNFC register as "1". All bits of PNCR and PNFC are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, all bits of an output latch are set to "1".

(1) PN0 (SCK0), PN3 (SCK1)

PN0 and PN3 are general-purpose I/O ports. It is also used as a SCK (clock I/O signal in SIO mode).

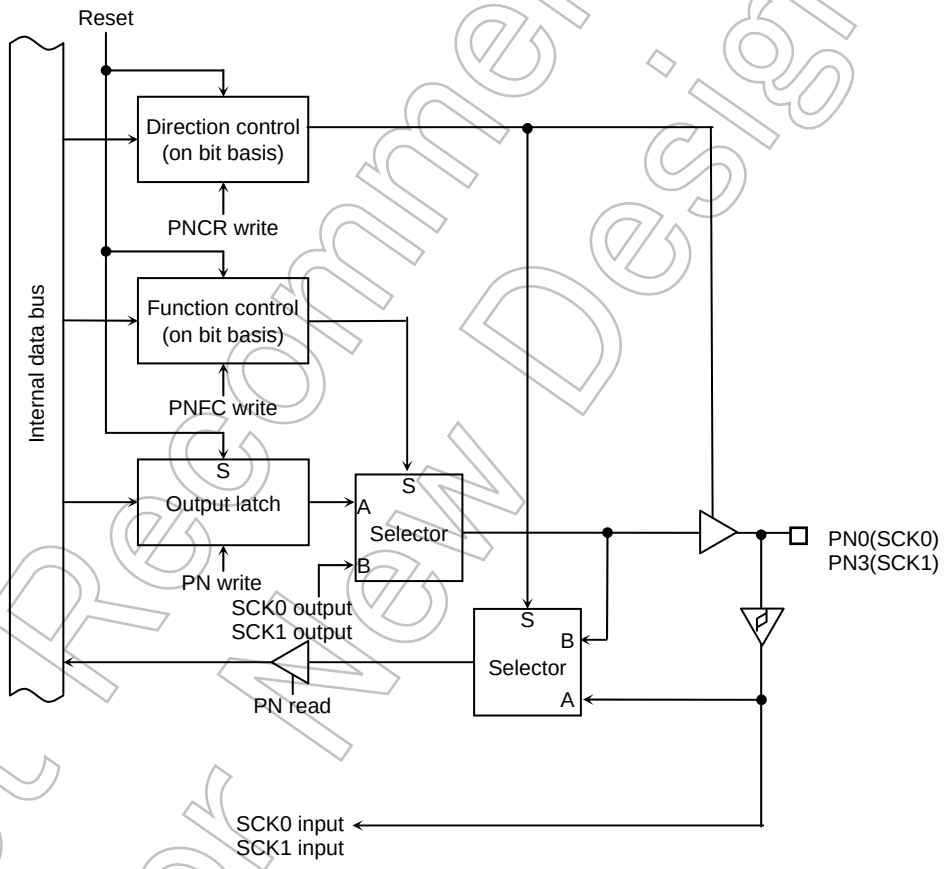

Figure 3.5.39 Port N (PN0, PN3)

(2) PN1 (SDA0/SO0), PN4 (SDA1/SO1)

PN1 and PN4 are general-purpose I/O ports. It is also used as a SO (data output signal in SIO mode), and SDA (data signal in I²CBUS mode). Moreover, these ports serve as an open drain output.

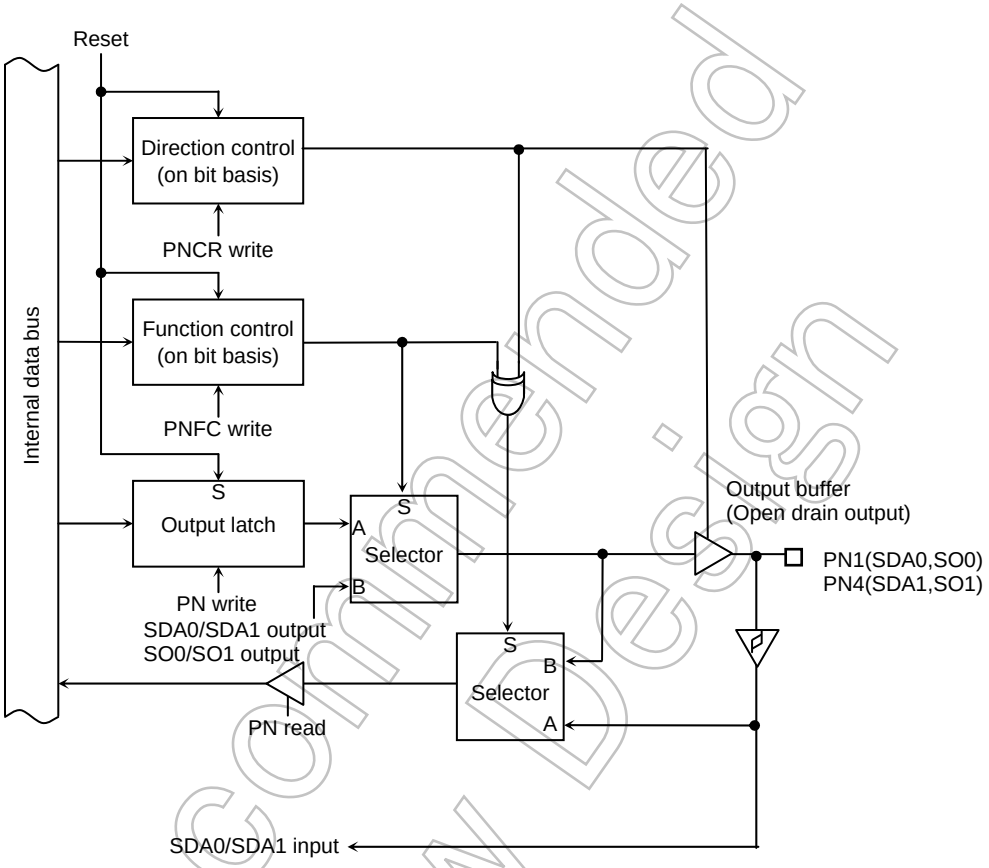

Figure 3.5.40 Port N (PN1, PN4)

(3) PN2 (SCL0/SI0), PN5 (SCL1/SI1)

PN2 and PN5 are general-purpose I/O ports. It is also used as a SI (data input signal in SIO mode), and SCL (clock signal in I²CBUS mode). Moreover, these ports serve as an open drain output.

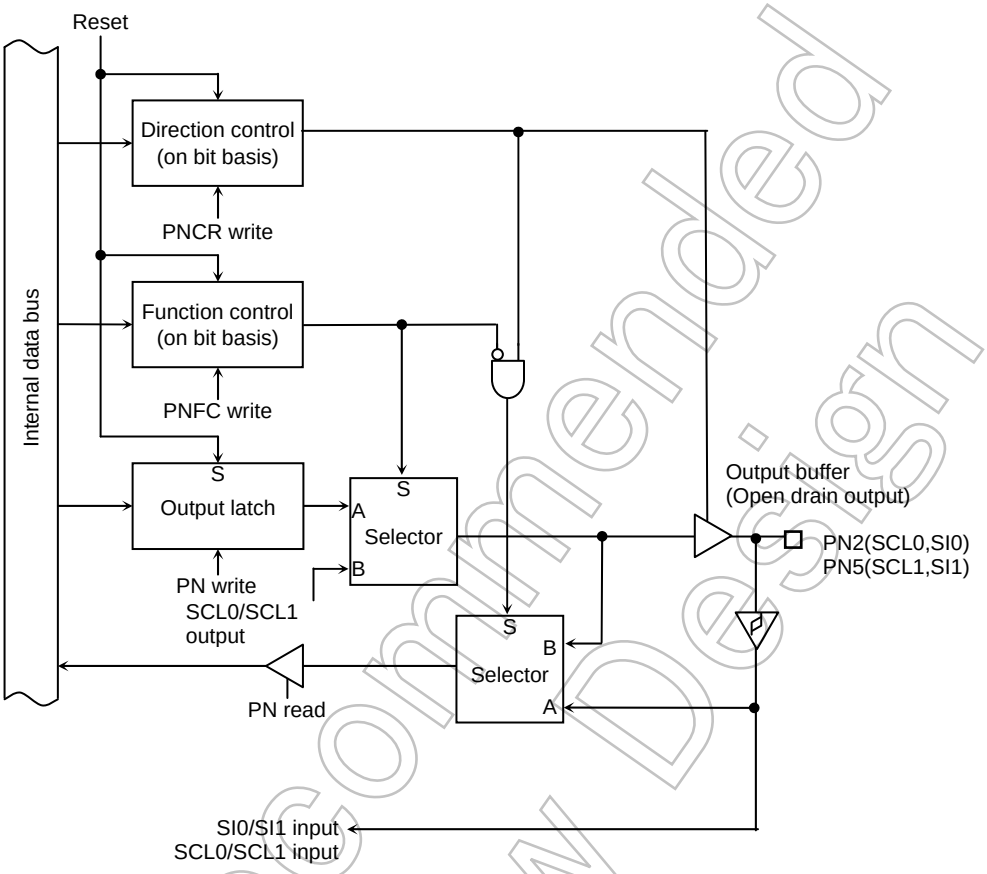

Figure 3.5.41 Port N (PN2, PN5)

Figure 3.5.42 Register for Port N

3.6 Memory Controller

3.6.1 Functional Overview

The TMP92CY23/CD23A has a memory controller with a following features to control four programmable address spaces:

(1) Four programmable address spaces

The MEMC can specify a start address and a block size for each of he four memory spaces.

- SRAM or ROM: All CS spaces (CS0 to CS3) can be assigned.
- Page-ROM: Only the CS2 space can be assigned.

(2) Memory specification

The MEMC can specify the type of memory, SRAM or ROM, to associate with the selected address spaces.

(3) Data bus size specification

The data bus width is selectable from 8 and 16 bits for the respective chip select spaces.

(4) Wait control

The number of wait states to be inserted into an external bus cycle is determined by the wait state bits of the control register and the $\overline{WAIT}$ input pin. The number of wait states of a read cycle and that of a write cycle can be specified individually. The number of wait states can be selected from the following 6 options.

0 wait state, 1 wait state, 2 wait states, 3 wait states, 4 wait states N wait states (controlled by the $\overline{WAIT}$ pin)

3.6.2 Control Registers and Memory Access Operations After Reset

This section describes the registers to control the memory controller, their reset states and the necessary settings after reset.

(1) Control Registers

The control registers of the memory controller are listed below.

- Control registers: BnCSH/BnCSL (n = 0 to 3, EX)
  Configures the basic settings of the memory controller, such as the memory type, specification and the number of wait states to be inserted into a read or write cycle.
- Memory Start Address register: MSARn (n = 0 to 3)
  Specifies a start address for a selected address space.
- Memory Address Mask register: MAMR (n = 0 to 3)
  Specifies a block size for a selected address space.
- Page ROM Control register: PMEMCR
  Selects a method of accessing Page-ROM.

(2) Memory Access Operations After Reset

Upon reset, only the control registers (B2CSH and B2CSL) for the CS2 space automatically becomes effective.

Then, the bus width specification bits of the control register for the CS2 space becomes undefined, this bit must be set before accessing the external CS2 spaces.

At the same time, the address range ebtween 000000H and FFFFFFH is defined as the CS2 space (The B2CSH<B2M> is cleared to “0”).

Then, the address spaces are configured by MSARn and MAMRn. The BnCSH and BnCSL registers are also set up.

The BnCSH<BnE> must be set to “1” to enable these settings.

3.6.3 Basic Functions and Register Settings

This section describes some of the memory controller functions, such as setting the address range for each address space, associating memory to the selected and setting the number of wait states to be inserted.

(1) Programming chip select spaces

The address space is specified by two registers.

The Memory Start Address Register (MSARn) specify the start address for the CS spaces. The memory controller compares the register value and the address every bus cycle. The address bit which is masked by the MAMRn is not compared by the memory controller. The CS spaces size is determined by setting the Memory Address Mask Register. The set value in the register is compared with the CS spaces on the bus. If the result is a match, the memory controller sets the chip select signal ($\overline{CSn}$) to "low".

(i) Memory Start Address Registers

The MSAR0 to MSAR3 specify the start addresses for the CS0 to CS3 spaces. The <MS23:MS16> bits specify the upper 8 bits (A23 to A16) of the start address. The lower 16 bits of the start address (A15 to A0) are assumed to be 0000H. Accordingly, the start address can only be a multiple of 64 Kbytes, ranging from 000000H to FF0000H.

(ii) Memory Address Mask Registers

The Memory Address Mask Register determines whether an address bit is compared or not. In register setting, "0" is "compare", and "1" is "do not compare".

The address bits that can be set depends on the CS spaces.

CS0: A20 to A8

CS1: A21 to A8

CS2 to CS3: A22 to A15

The upper bits are always compared. The CS space size is determined by the result of the comparison.

The size to be set depending on the CS space is as follows.

Size (bytes) / CS Area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
CS0	○	○	○	○	○	○	○	○	○		
CS1	○	○		○	○	○	○	○	○	○	
CS2 to CS3			○	○	○	○	○	○	○	○	○

Note: After reset, only the control register for the CS2 space is effective. The control register for the CS2 space has the B2M bit. If the B2M bit is cleared to "0", the address range between 000000H and FFFFFFH is defined as the CS2 space. (The B2M bit is cleared to "0" after reset.) By setting the B2CSH<B2M> bit to "1", the start address and the block size can be arbitrarily specified, as in the other spaces.

(iii) Example of register setting

To set the CS1 space 512 bytes from address 110000H, set the register as follows.

MSAR1 Register

	7	6	5	4	3	2	1	0
Bit symbol	M1S23	M1S22	M1S21	M1S20	M1S19	M1S18	M1S17	M1S16
Specified value	0	0	0	1	0	0	0	1

M1S23 to M1S16 bits of the MSAR1 correspond to address A23 to A16.

A15 to A0 are cleared to "0". Therefore, if MSAR1 is set to the above mentioned value, the start address of the CS space is set to address 110000H.

MAMR1 Register

	7	6	5	4	3	2	1	0
Bit symbol	M1V21	M1V20	M1V19	M1V18	M1V17	M1V16	M1V15 to M1V9	M1V8
Specified value	0	0	0	0	0	0	0	1

M1V21 to M1V16 and M1V8 bits of the MAMR1 are set whether addresses A21 to A16 and A8 are compared or not. In register setting, "0" is "compare", and "1" is "do not to compare". M1V15 to M1V9 bits determine whether addresses A15 to A9 are compared or not with bit 1. A23 and A22 are always compared.

When set as above, A23 to A9 are compared with the values that is set as the start addresses. Therefore, the 512 bytes (addresses 110000H to 1101FFH) are set as CS1 spaces. If it is compared with the addresses on the bus, the chip select signal $\overline{CS1}$ is set to "LOW".

A23 to A21 are always compared with CS0 spaces. Whether A20 to A8 are compared or not is determined by the register.

Similarly, A23 is always compared with CS2 space to CS3 space. Whether A22 to A15 are compared or not is determined by the register.

Note: When the specified address space overlaps with the on-chip memory area, priority oreder of address spaces are as follows.

On-chip I/O > On-chip memory > CS0 space > CS1 space > CS2 space > CS3 space

The BEXCSL and BEXCSH registers specify the data bus width and number of wait states when an address outside the $\overline{CS0}$ to $\overline{CS3}$ spaces ($\overline{CSEX}$ space) is accessed. These registers are always enabled for the $\overline{CSEX}$ space.

(2) Memory specification

Setting the <BnOM1:BnOM0> bits specifies the memory type that is associated with each address spaces. The interface signal that corresponds to the specified memory type is generated. The memory type is specified as follows:

<BnOM1: BnOM0> Bit (BnCSH register)

BnOM1	BnOM0	Memory type
0	0	SRAM/ROM (Default)
0	1	Reserved
1	0	Reserved
1	1	Reserved

(3) Data bus width specification

The data bus width can be specified for each address space by the BnCSH<BnBUS1:BnBUS0> bits as follows.

<BnBUS1: BnBUS0> Bit (BnCSH register)

BnBUS1	BnBUS0	Bus Width
0	0	8-bit bus mode (Note 2)
0	1	16-bit bus mode
1	0	Reserved
1	1	Reserved

As described above, the TMP92CY23/CD23A supports dinamic bus sizing, which allows the controller to transfer operands to or from the selected address spaces while automatically determining the data bus width. On which part of the data bus the data is actually placed is determined by the data size, bus width and start address. The table below provides a detailed description of the actual bus operation.

Note1: If two memories with different bus widths are assigned to consecutive addresses, do not execute an instruction that accesses the addresses crossing the boundary between those memories. Otherwise, a read/write operation might not be performed correctly

Note2: Upon reset, the bus width specification bits of the control register for the CS2 space (B2CSH <B2BUS1:0>) becomes undefined, this bit must be set before accessing the external CS2 spaces.

Operand Data Size (Bit)	Operand Start Address	Memory Data Size (Bit)	CPU Address	CPU Data			
				D32 to D24	D23 to D16	D15 to D8	D7 to D0
8	4n + 0	8/16	4n + 0	xxxxx	xxxxx	xxxxx	b7 to b0
	4n + 1	8	4n + 1	xxxxx	xxxxx	xxxxx	b7 to b0
		16	4n + 1	xxxxx	xxxxx	b7 to b0	xxxxx
	4n + 2	8/16	4n + 2	xxxxx	xxxxx	xxxxx	b7 to b0
	4n + 3	8	4n + 3	xxxxx	xxxxx	xxxxx	b7 to b0
		16	4n + 3	xxxxx	xxxxx	b7 to b0	xxxxx
16	4n + 0	8	(1) 4n + 0	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 1	xxxxx	xxxxx	xxxxx	b15 to b8
		16	4n + 0	xxxxx	xxxxx	b15 to b8	b7 to b0
	4n + 1	8	(1) 4n + 1	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 2	xxxxx	xxxxx	xxxxx	b15 to b8
		16	(1) 4n + 1	xxxxx	xxxxx	b7 to b0	xxxxx
			(2) 4n + 2	xxxxx	xxxxx	xxxxx	b15 to b8
	4n + 2	8	(1) 4n + 2	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 1	xxxxx	xxxxx	xxxxx	b15 to b8
		16	4n + 2	xxxxx	xxxxx	b15 to b8	b7 to b0
	4n + 3	8	(1) 4n + 3	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 4	xxxxx	xxxxx	xxxxx	b15 to b8
		16	(1) 4n + 3	xxxxx	xxxxx	b7 to b0	xxxxx
			(2) 4n + 4	xxxxx	xxxxx	xxxxx	b15 to b8

	4n + 2	8	(1) 4n + 2	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 3	xxxxx	xxxxx	xxxxx	b15 to b8
			(3) 4n + 4	xxxxx	xxxxx	xxxxx	b23 to b16
			(4) 4n + 5	xxxxx	xxxxx	xxxxx	b31 to b24
		16	(1) 4n + 2	xxxxx	xxxxx	b15 to b8	b7 to b0
			(2) 4n + 4	xxxxx	xxxxx	b31 to b24	b23 to b16
	4n + 3	8	(1) 4n + 3	xxxxx	xxxxx	xxxxx	b7 to b0
			(2) 4n + 4	xxxxx	xxxxx	xxxxx	b15 to b8
			(3) 4n + 5	xxxxx	xxxxx	xxxxx	b23 to b16
			(4) 4n + 6	xxxxx	xxxxx	xxxxx	b31 to b24
		16	(1) 4n + 3	xxxxx	xxxxx	b7 to b0	xxxxx
			(2) 4n + 4	xxxxx	xxxxx	b23 to b16	b15 to b8
			(3) 4n + 6	xxxxx	xxxxx	xxxxx	b31 to b24

xxxxx: The input data placed on the data bus indicated by this symbol is ignored during a read operation. During a write operation, the bus is in the high-impedance state, and the write strobe signal remains inactive.

(4) Wait control

The external bus cycle completes in two states at minimum (100 ns at f_{SYS} = 20 MHz) without inserting a wait state.

Setting up the BnCSL<BnWW2:BnWW0> specifies the number of wait states to be inserted in a write cycle, and setting the <BnWR2:BnWR0> bits specifies the number of wait states to be inserted in a read cycle. The external bus cycle can be programmed as follows;

BnCSL Register <BnWW2:BnWW0>/<BnWR2:BnWR0>

BnWW2	BnWW1	BnWW0	Number of Wait States
BnWR2	BnWR1	BnWR0	
0	0	1	2states (0 wait state), fixed wait-state mode
0	1	0	3states (1 wait state), fixed wait-state mode (Default)
1	0	1	4states (2 wait states), fixed wait-state mode
1	1	0	5states (3 wait states), fixed wait-state mode
1	1	1	6states (4 wait states), fixed wait-state mode
0	1	1	$\overline{\text{WAIT}}$ pin input mode
Other than the above			Reserved

(i) Fixed wait-state mode

The bus cycle is completed in the specified number of states. The number of states can be selected from 2 (0 wait state) through 6 (4 wait states).

(ii) $\overline{\text{WAIT}}$ pin input mode

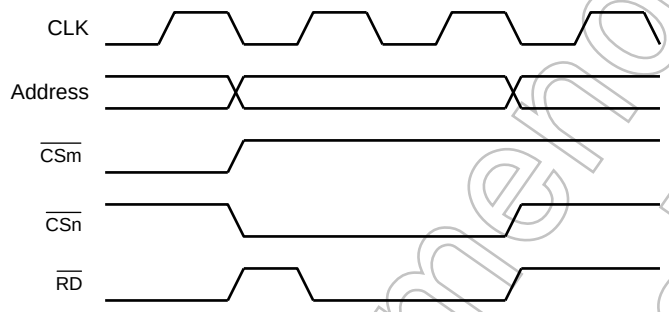
In this mode, the $\overline{\text{WAIT}}$ signal is sampled. A wait state is continued to be inserted while the $\overline{\text{WAIT}}$ signal is sampled active. The minimum bus cycle in this mode is two states. The bus cycle is completed if the wait signal is non-active ("High" level) at the second states. The bus cycle is extended as the wait signal remains active after second states.

(5) Insert Recovery cycle

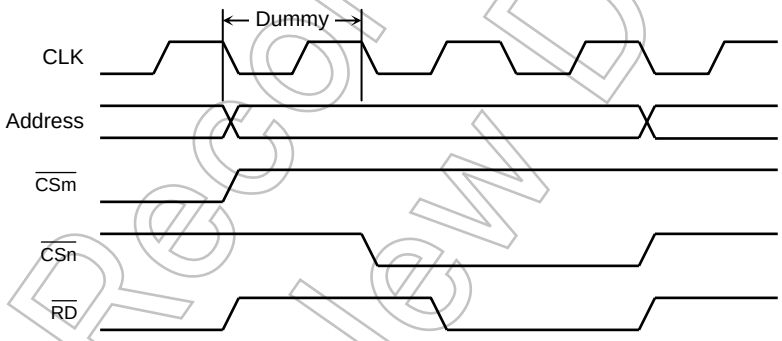
If the plural memory which Data-output-floating-time (t_{DF}) is long (the external ROM and etc.) are set, it is necessary to consider each other's t_{DF} times. However, if BnCSH<BnREC> is set, you can insert dummy cycle of 1-state just before the first bus cycle which start accessing to other CS space.

BnCSH <BnREC>	
0	No dummy cycle is inserted (Default).
1	Dummy cycle is inserted.

- When no dummy cycle is inserted (0 wait state)

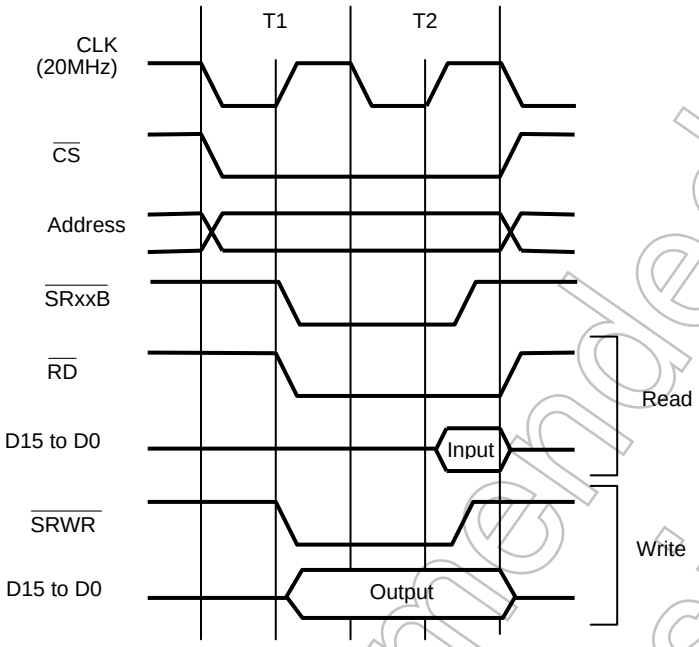


- When a dummy cycle is inserted (0 wait state)

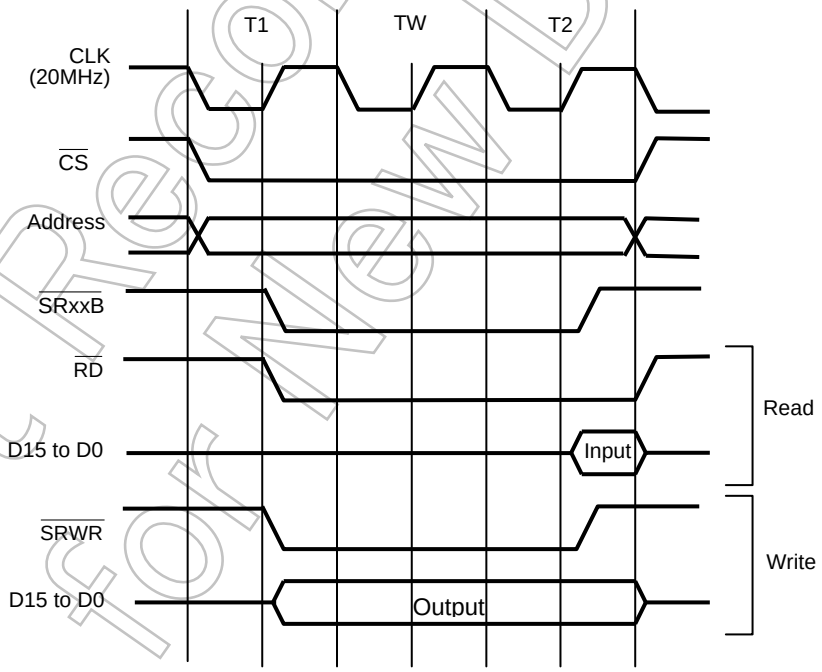


(6) Basic bus timing

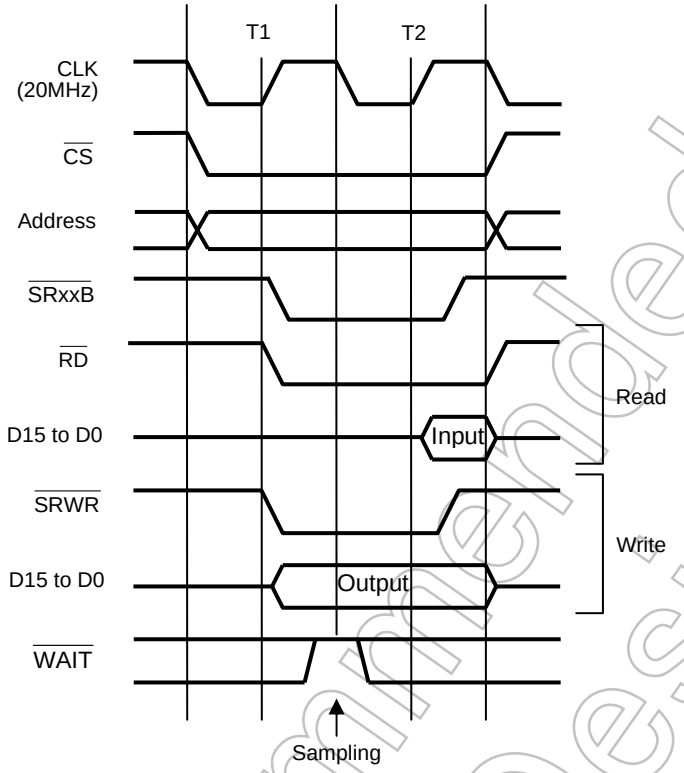
- External bus read/write bus cycle (0 wait state)



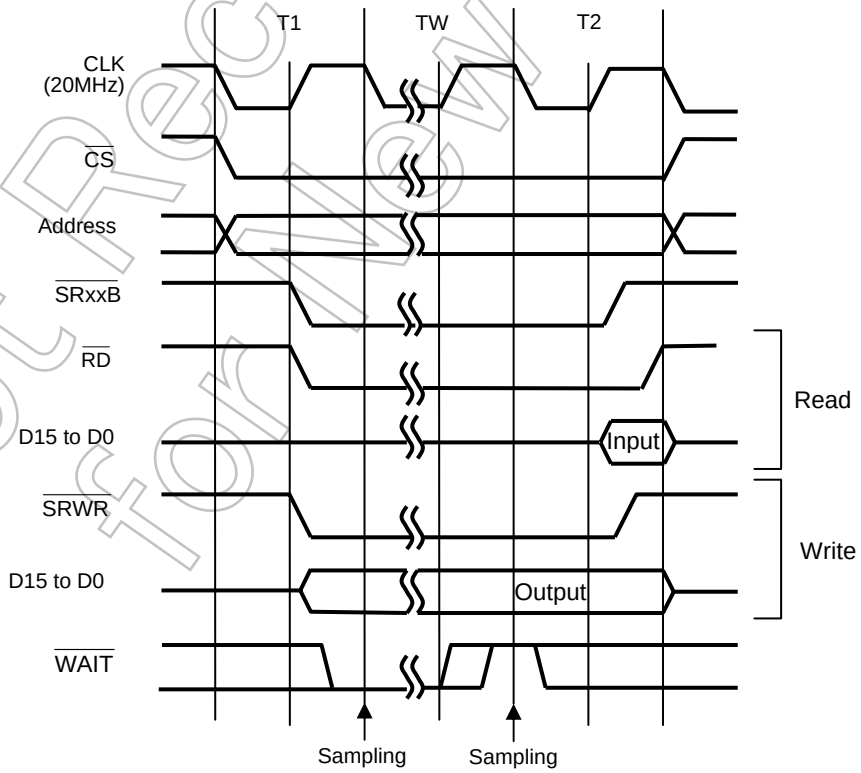
- External bus read/write bus cycle (1 wait state)



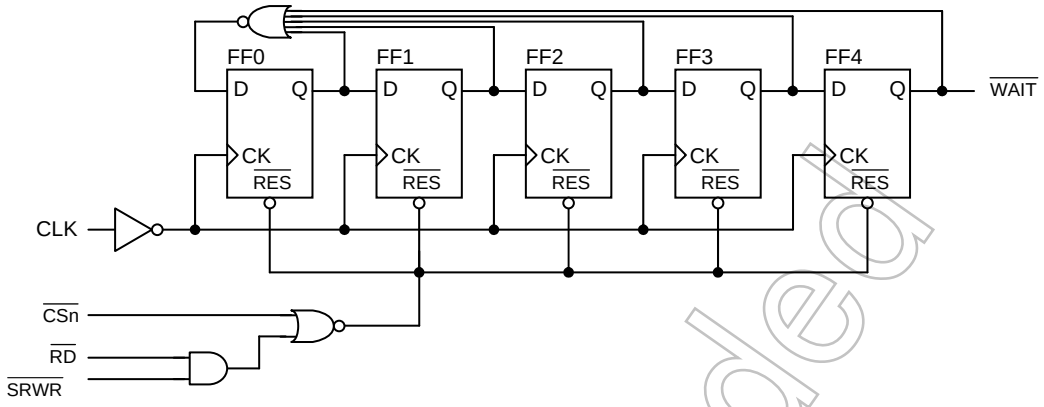
- External bus read/write cycle (0 wait state at $\overline{\text{WAIT}}$ pin input mode)

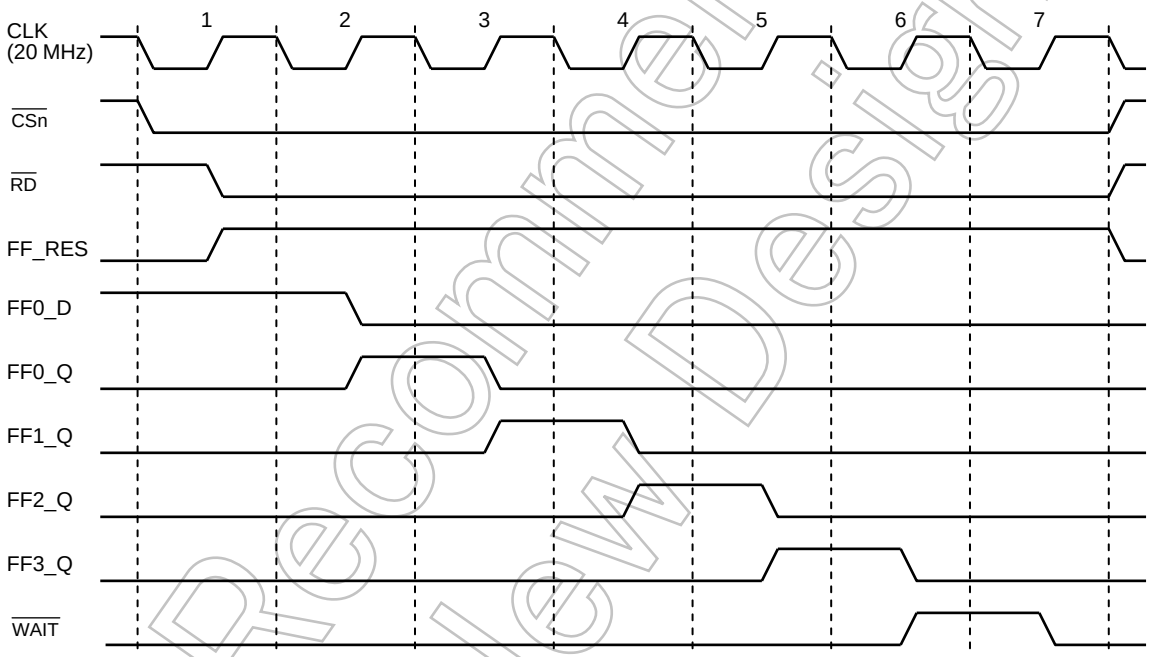


- External bus read/write cycle (n wait state at $\overline{\text{WAIT}}$ pin input mode)



- Example of $\overline{\text{WAIT}}$ input cycle (5 wait state)





3.6.4 Controlling the Page Mode Access to ROM

This section describes page mode access operations to ROM and the required register settings. The page mode operation to ROM is specified by PMEMCR.

(1) Operations and register settings

The TMP92CY23/CD23A supports page mode accesses to ROM. Only the CS2 space can be configured for this mode of access.

The page mode operation to ROM is specified by the Page ROM Control register, PMEMCR.

Setting the PMEMCR<OPGE> bit to "1" sets the mode of memory access to the CS space to page mode.

The number of cycles required for a read cycle is specified by the PMEMCR<OPWR1:0> bits.

PMEMCR<OPWR1:OPWR0>

OPWR1	OPWR0	Number of Cycles in Page Mode
0	0	1 cycle (n-1-1-1 mode) (n ≥ 2)
0	1	2 cycle (n-2-2-2 mode) (n ≥ 3)
1	0	3 cycle (n-3-3-3 mode) (n ≥ 4)
1	1	Reserved

Note: Specify the number of wait state "n" using the control register (B2CSL) for CS2 space.

The page size (the number of bytes) of ROM as seen from the CPU is determined by PMEMCR<PR1:PR0>. When the specified page boundary is reached, the controller terminates the page read operation. The first data of the next page is read in the normal mode. Then, the following data is read again in page mode.

PMEMCR <PR1:PR0>

PR1	PR0	ROM Page Size
0	0	64 bytes
0	1	32 bytes
1	0	16 bytes
1	1	8 bytes

(2) Signal timing pulse

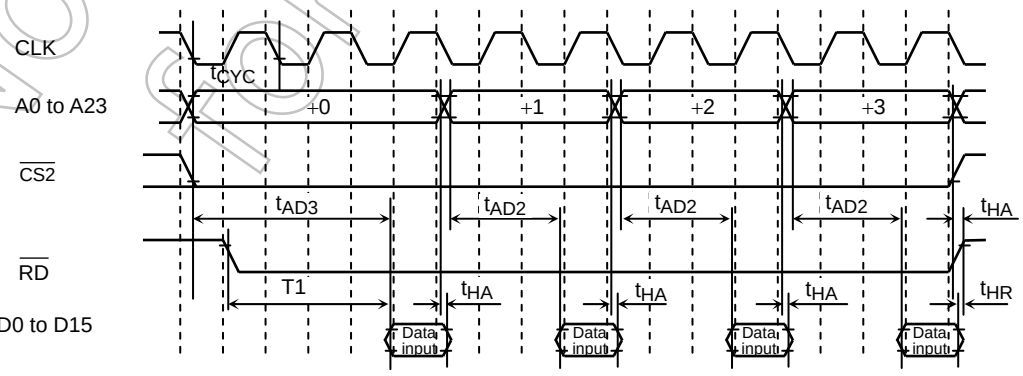


Figure 3.6.1 Timing Pulse diagram (when using a 8-bit setting)

3.6.5 List of Registers

The memory control registers and the settings are described as follows. For the addresses of the registers, see Section 5 “Table of Special Function Registers (SFRs)”.

(1) Control registers

The control register is a pair of BnCSL and BnCSH. (“n” is a number of the CS space.) BnCSL has the same configuration regardless of the CS space. In BnCSH, only B2CSH which is corresponded to the CS2 space has a different configuration from the others.

BnCSL

	7	6	5	4	3	2	1	0
Bit symbol		BnWW2	BnWW1	BnWW0		BnWR2	BnWR1	BnWR0
Read/Write		W				W		
Reset State		0	1	0		0	1	0

<BnWW2:0> Specifies the number of write waits.

001 = 2 states (0 waits) access
010 = 3 states (1 wait) access
101 = 4 states (2 waits) access
110 = 5 states (3 waits) access
111 = 6 states (4 waits) access
011 = $\overline{\text{WAIT}}$ pin input mode
Others = (Reserved)

<BnWR2:0> Specifies the number of read waits.

001 = 2 states (0 waits) access
010 = 3 states (1 wait) access
101 = 4 states (2 waits) access
110 = 5 states (3 waits) access
111 = 6 states (4 waits) access
011 = $\overline{\text{WAIT}}$ pin input mode
Others = Reserved

B2CSH

	7	6	5	4	3	2	1	0
Bit symbol	B2E	B2M	−	B2REC	B2OM1	B2OM0	B2BUS1	B2BUS0
Read/Write	W							
Reset State	1	0	0	0	0	0	Undefined	Undefined

<B2E>: Enable bit

0 = No chip select signal output.
1 = Chip select signal output (Default).
Note: After reset, only the enable bit <B2E> of B2CS register is valid (“1”).

<B2M>: CS space specification

0 = Sets the CS2 space to addresses 000000H to FFFFFFH (Default).
1 = Sets the CS2 space to programmable.
Note: After reset, the CS2 space is set to addresses 000000H to FFFFFFH.

<B2REC>: Sets the dummy cycle for data output recovery time.

0 = Not insert a dummy cycle (Default).
1 = Insert a dummy cycle.

<B2OM1:0>

00 = SRAM or ROM (Default)
Others = Reserved

<B2BUS1:0> Sets the data bus width.

00 = 8 bits
01 = 16 bits
10 = Reserved
11 = Reserved
Note: The value of <B2BUS> bit is set according to the state of AM<1:0> pin after reset.

BnCSH (n = 0, 1, 3)

	7	6	5	4	3	2	1	0
Bit symbol	BnE			BnREC	BnOM1	BnOM0	BnBUS1	BnBUS0
Read/Write	W			W				
Reset State	0			0	0	0	0	0

<BnE>: Enable bit

0 = No chip select signal output (Default).

1 = Chip select signal output.

Note: After reset, only the enable bit B2E of B2CS register is valid (“1”).

<BnREC>: Sets the dummy cycle for data output.

0 = Not insert a dummy cycle (Default).

1 = Insert a dummy cycle.

<BnOM1:0>

00 = SRAM or ROM (Default)

01 = Reserved

10 = Reserved

11 = Reserved

<BnBUS1:0> Sets the data bus width.

00 = 8 bits (Default)

01 = 16 bits

10 = Reserved

11 = Reserved

BEXCSL

	7	6	5	4	3	2	1	0
Bit symbol		BEXWW2	BEXWW1	BEXWW0		BEXWR2	BEXWR1	BEXWR0
Read/Write		W				W		
Reset State		0	1	0		0	1	0

<BEXWW2:0> Specifies the number of write waits.

001 = 2 states (0 waits) access

010 = 3 states (1 wait) access

101 = 4 states (2 waits) access

110 = 5 states (3 waits) access

111 = 6 states (4 waits) access

011 = $\overline{\text{WAIT}}$ pin input mode

Others = (Reserved)

<BEXWR2:0> Specifies the number of read waits.

001 = 2 states (0 waits) access

010 = 3 states (1 wait) access

101 = 4 states (2 waits) access

110 = 5 states (3 waits) access

111 = 6 states (4 waits) access

011 = $\overline{\text{WAIT}}$ pin input mode

Others = Reserved

BEXCSH

	7	6	5	4	3	2	1	0
Bit symbol				BEXREC	BEXOM1	BEXOM0	BEXBUS1	BEXBUS0
Read/Write				W				
Reset State				0	0	0	0	0

<BEXOM1:0>

00 = SRAM or ROM (Default)

01 = Reserved

10 = Reserved

11 = Reserved

<BEXBUS1:0>

00 = 8 bits (Default)

01 = 16 bits

10 = Reserved

11 = Reserved

(2) Block address register

A start address and an address area of the CS spaces are specified by the Memory Start Address Register (MSARn) and the Memory Address Mask Register (MAMRn). The memory start address register sets all start address similarly regardless of the CS spaces.

The bit to be set by the MAMRn is depended on the CS spaces.

MSARn (n = 0 to 3)

	7	6	5	4	3	2	1	0
Bit symbol	MnS23	MnS22	MnS21	MnS20	MnS19	MnS18	MnS17	MnS16
Read/Write	R/W							
Reset State	1	1	1	1	1	1	1	1

<MnS23:16> Sets a start address.

Sets the start address of the CS spaces. <MnS23:16> are corresponding to the address A23 to A16.

MAMR0

	7	6	5	4	3	2	1	0
Bit symbol	M0V20	M0V19	M0V18	M0V17	M0V16	M0V15	M0V14 to M0V9	M0V8
Read/Write	R/W							
Reset State	1	1	1	1	1	1	1	1

<M0V20:8>

Enables or masks comparison of the addresses. <M0V20:8> are corresponding to addresses A20 to A8. <M0V14:9> are corresponding to address A14 to A9 by 1 bit. If “0” is set, the comparison between the value of the address bus and the start address is enabled. If “1” is set, the comparison is masked.

MAMR1

	7	6	5	4	3	2	1	0
Bit symbol	M1V21	M1V20	M1V19	M1V18	M1V17	M1V16	M1V15 to M1V9	M1V8
Read/Write	R/W							
Reset State	1	1	1	1	1	1	1	1

<M1V21:8>

Enables or masks comparison of the addresses. <M1V21:8> are corresponding to addresses A21 to A8. <M1V15:9> are corresponding to address A15 to A9 by 1 bit. If “0” is set, the comparison between the value of the address bus and the start address is enabled. If “1” is set, the comparison is masked.

MAMRn (n = 2 to 3)

	7	6	5	4	3	2	1	0
Bit symbol	MnV22	MnV21	MnV20	MnV19	MnV18	MnV17	MnV16	MnV15
Read/Write	R/W							
Reset State	1	1	1	1	1	1	1	1

<MnV22:15>

Enables or masks comparison of the addresses. <MnV22:15> are corresponding to addresses A22 to A15. If "0" is set, the comparison between the value of the address bus and the start address is enabled. If "1" is set, the comparison is masked.

After a reset, MASR0 to MSAR3 and MSAR0 to MAMR3 are set to "FFH". B0CSH<B0E>, B1CSH<B1E>, and B3CSH<B3E> are reset to "0". This disabling the CS0, CS1, and CS3 areas. However, B2CSH<B2M> is reset to "0" and B2CSH<B2E> to "1", and CS2 is enabled 000000H to FFFFFFH. Also the bus width and number of waits specified in BEXCSH/L are used for accessing address except the specified CS0 to CS3 area.

(3) Page ROM control register (PMEMCR)

The page ROM control register sets page ROM accessing. ROM page accessing is executed only in CS2 space.

PMEMCR

	7	6	5	4	3	2	1	0
Bit symbol				OPGE	OPWR1	OPWR0	PR1	PR0
Read/Write				R/W				
Reset State				0	0	0	1	0

<OPGE> enable bit

0 = No ROM page mode accessing (Default)

1 = ROM page mode accessing

<OPWR1:0> Specifies the number of waits.

00 = 1 state (n-1-1-1 mode) ($n \geq 2$) (Default)

01 = 2 states (n-2-2-2 mode) ($n \geq 3$)

10 = 3 states (n-3-3-3 mode) ($n \geq 4$)

11 = Reserved

Note: Set the number of waits "n" to the control register (BnCSL) in CS spaces.

<PR1:0> ROM page size

00 = 64 bytes

01 = 32 bytes

10 = 16 bytes (Default)

11 = 8 bytes

Table 3.6.1 Control Register (1/2)

(0159H)	Read/Write				W				
	Reset State				0	0	0	0	0
BEXCSL	Bit symbol		BEXWW2	BEXWW1	BEXWW0		BEXWR2	BEXWR1	BEXWR0
(0158H)	Read/Write		W				W		
	Reset State		0	1	0		0	1	0
PMEMCR	Bit symbol				OPGE	OPWR1	OPWR0	PR1	PR0
(0166H)	Read/Write				R/W				
	Reset State				0	0	0	1	0

Note 1: Always write “0”.

Note 2: A read-modify-write operation cannot be performed in BnCSL, BnCSH registers (n=0 to 3, EX).

Note3: Upon reset, these bits become undefined, this bit must be set before accessing the CS2 spaces.

3.6.6 Notes

(1) Timing for the $\overline{CS}$ and $\overline{RD}$ signals.

If the load capacitance of the $\overline{RD}$ (Read) signal line is greater than that of the $\overline{CS}$ (Chip Select) signal line, the deassertion timing of the read signal is delayed, which may lead to an unintentional extension of a read cycle. Such an unintended read cycle extention, which is indicated as (a) in Figure 3.6.2 may cause a problem.

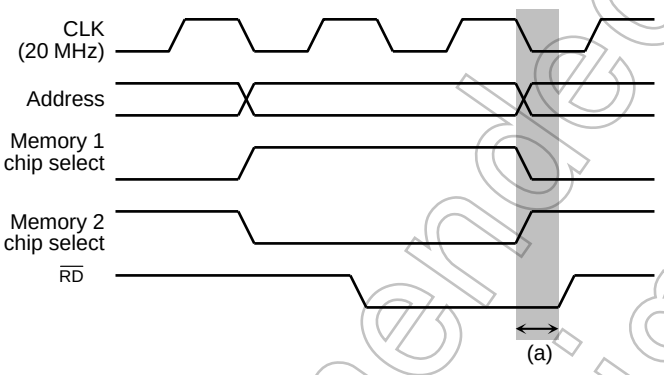

Figure 3.6.2 Delay Read Cycle of When the Read Signal is Delayed

Example: When using an externally connected flash EEPROM whose commands are compatible with the standard JEDEC commands, the toggle bit may not be read correctly. If the rising edge of the read signal in the cycle immediately preceding the flash EEPROM access cycle does not occur in time, a read cycle may be extended unintentilnally as indicated as indicated as (b) in Figure 3.6.3.

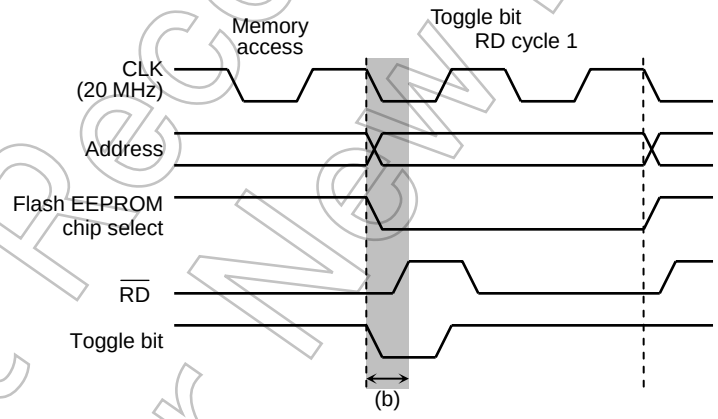

Figure 3.6.3 Flash EEPROM Toggle Bit Read Cycle

When the toggle bit is inverted due to this unexpected read cycle extension, the CPU read the toggle bit properly and it always reads the same value from the toggle bit.

To avoid this situation, it is recommended to perform data polling.

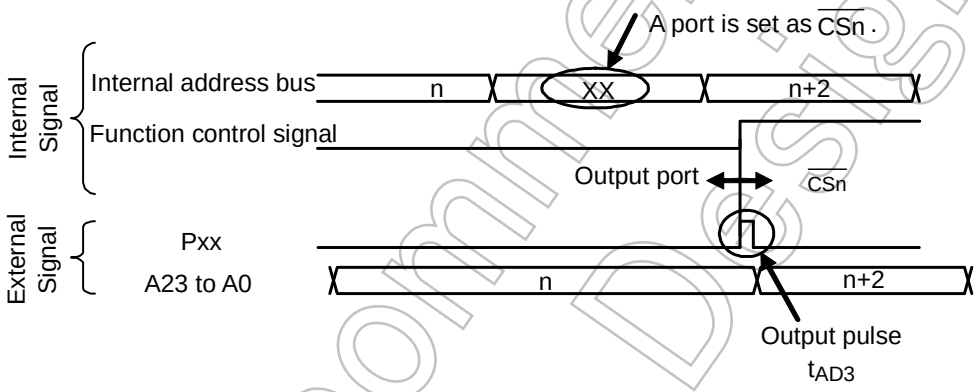
(2) The cautions at the time of the functional change of a $\overline{CSn}$.

A chip select signal output has the case of a combination terminal with a general-purpose port function. In this case, an output latch register and a function control register are initialized by the reset action, and an object terminal is initialized by the port output ("1" or "0") by it.

Functional change

Although an object terminal is changed from a port to a chip select signal output by setting up a function control register (PnFC register), the short pulse for several ns may be outputted to the changing timing. Although it does not become especially a problem when using the usual memory, it may become a problem when using a special memory.

* XX is a function register address.(When an output port is initialized by "0")

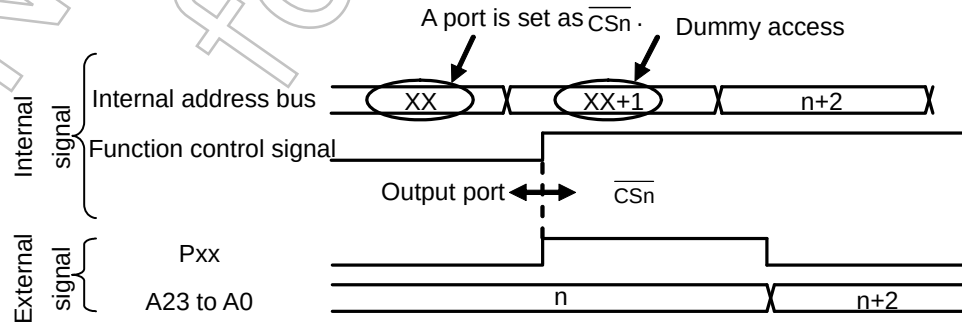


The measure by software

The countermeasures in S/W for avoiding this phenomenon are explained.

Since CS signal decodes the address of the access area and is generated, an unnecessary pulse is outputted by access to the object CS area immediately after setting it as a CSn function. Then, if internal area is accessed also immediately after setting a port as CS function, an unnecessary pulse will not output.

1. Prohibition of use of an NMI function
2. The ban on interruption under functional change (DI command)
3. A dummy command is added in order to carry out continuous internal access.
4. (Access to a functional change register is corresponded by 16-bit command. (LDW command))



3.7 8-Bit Timers (TMRA)

The TMP92CY23/CD23A features 6 built-in 8-bit timers (TMRA0-TMRA5). These timers are paired into three modules: TMRA01, TMRA23 and TMRA45. Each module consists of two channels and can operate in any of the following four operating modes.

- 8-bit interval timer mode
- 16-bit interval timer mode
- 8-bit programmable square wave pulse generation output mode (PPG: Variable duty cycle with variable period)
- 8-bit pulse width modulation output mode (PWM: Variable duty cycle with constant period)

Figure 3.7.1 to Figure 3.7.3 show block diagrams for TMRA01, TMRA23 and TMRA45.

Each channel consists of an 8-bit up counter, an 8-bit comparator and an 8-bit timer register. In addition, a timer flip-flop and a prescaler are provided for each pair of channels.

The operation mode and timer flip-flops are controlled by a five-byte SFR (special function registers).

Each of the three modules (TMRA01, TMRA23 and TMRA45) can be operated independently. All modules operate in the same manner; hence only the operation of TMRA01 is explained here.

Table 3.7.1 Registers and Pins for Each Module

Specification \ Module		TMRA01	TMRA23	TMRA45
External pin	Input pin for external clock	TA0IN (Shared with PC0)	None	None
	Output pin for timer flip-flop	TA1OUT (Shared with P80)	TA3OUT (Shared with P81)	TA5OUT (Shared with P83)
SFR (Address)	Timer RUN register	TA01RUN (1100H)	TA23RUN (1108H)	TA45RUN (1110H)
	Timer register	TA0REG (1102H) TA1REG (1103H)	TA2REG (110AH) TA3REG (110BH)	TA4REG (1112H) TA5REG (1113H)
	Timer mode register	TA01MOD(1104H)	TA23MOD(110CH)	TA45MOD(1114H)
	Timer flip-flop control register	TA1FFCR(1105H)	TA3FFCR(110DH)	TA5FFCR(1115H)

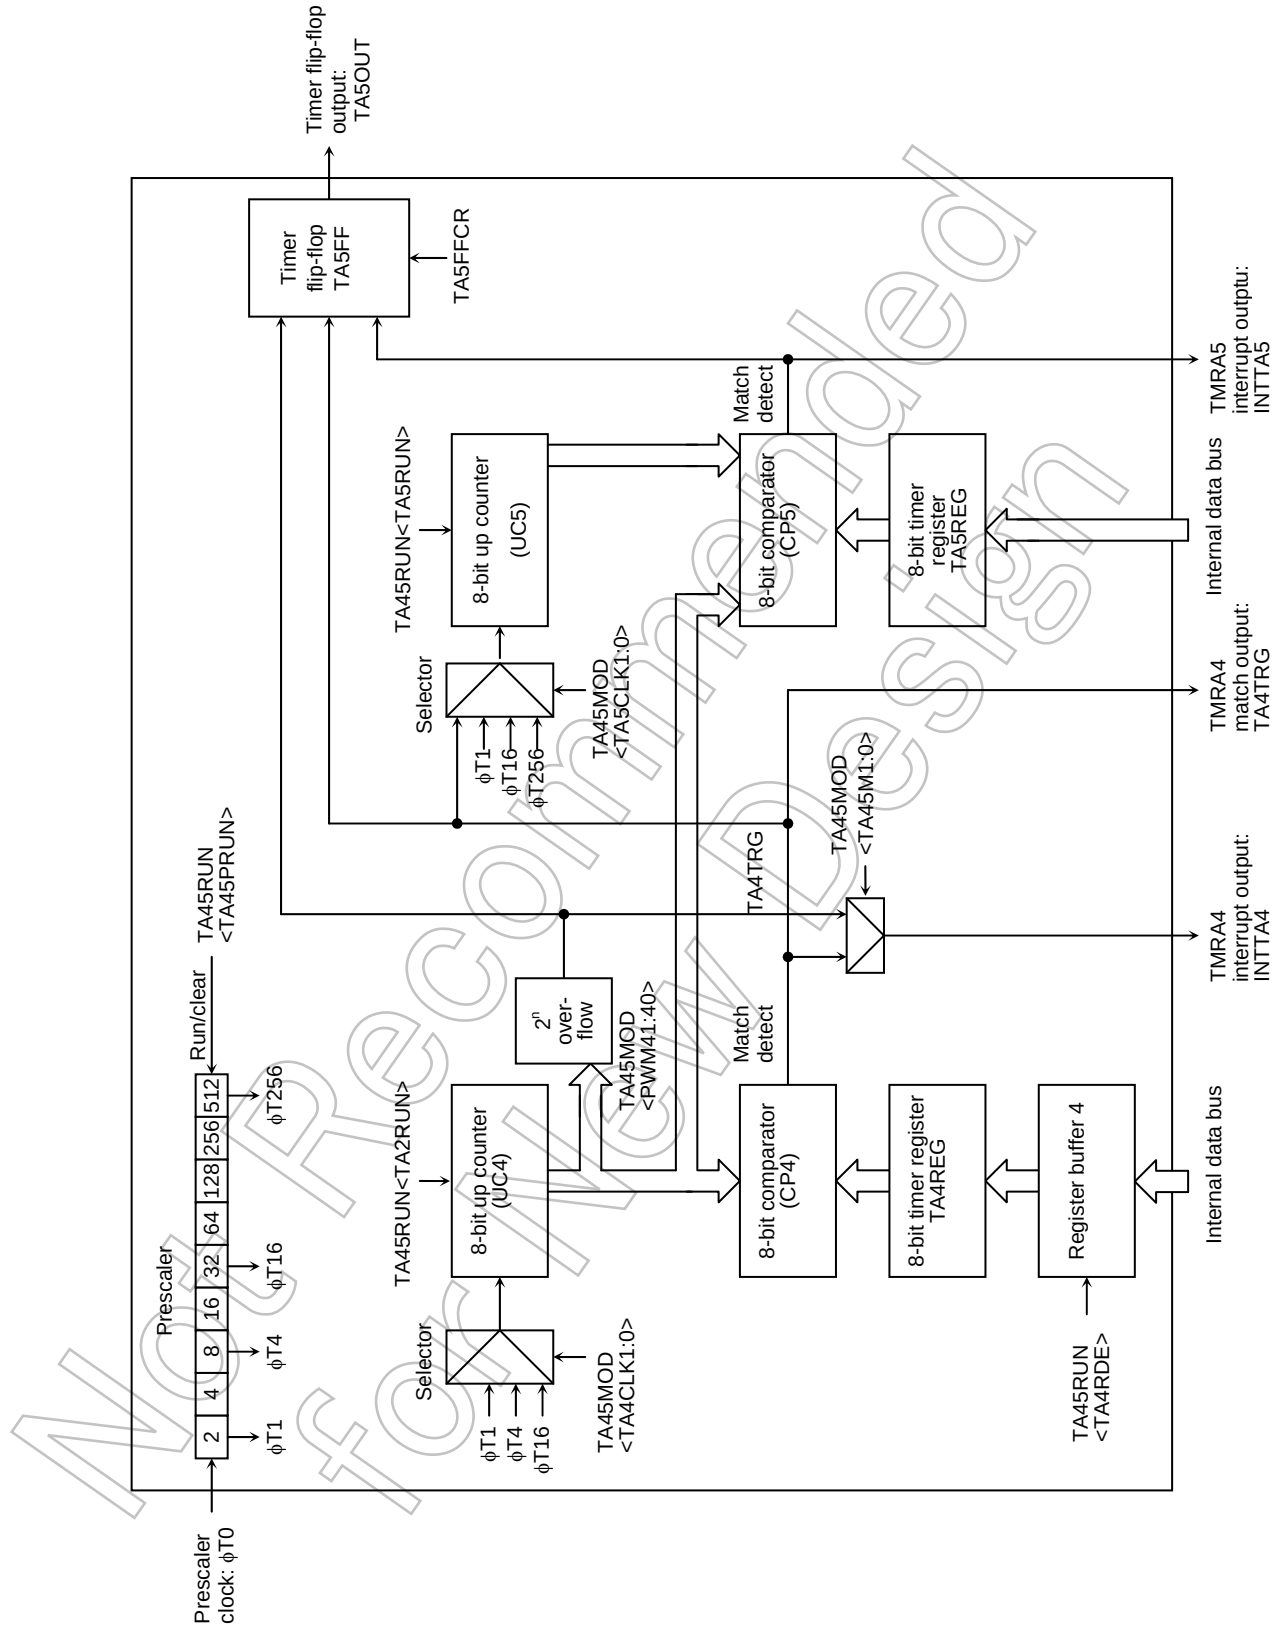

Figure 3.7.3 TMRA45 Block Diagram

3.7.2 Operation of Each Circuit

(1) Prescalers

A 9-bit prescaler generates the input clock to TMRA01.

The prescaler clock (ϕT0) is a divided clock (divided by 4) from the f_{FPH}.

The prescaler's operation can be controlled using TA01RUN <TA0PRUN> in the timer control register. Setting <TA0PRUN> to "1" starts the count; setting <TA0PRUN> to "0" clears the prescaler to "0" and stops operation. Table 3.7.2 shows the various prescaler output clock resolutions.

Table 3.7.2 Prescaler Output Clock Resolution

Clock Value SYSCR1 <GEAR2:0>	System clock SYSCR1 <SYSCK>	–	Timer counter input clock TMRA prescaler TAxMOD<TAxCLK1:0>			
			ϕT1(1/2)	ϕT4(1/8)	ϕT16(1/32)	ϕT256(1/512)
–	1 (fs)	1/4	fs/8	fs/32	fs/128	fs/2048
000 (1/1)	0 (fc)		fc/8	fc/32	fc/128	fc/2048
001 (1/2)			fc/16	fc/64	fc/256	fc/4096
010 (1/4)			fc/32	fc/128	fc/512	fc/8192
011 (1/8)			fc/64	fc/256	fc/1024	fc/16384
100 (1/16)			fc/128	fc/512	fc/2048	fc/32768

(2) Up counters (UC0 and UC1)

These are 8-bit binary counters which count up the input clock pulses for the clock specified by TA01MOD.

The input clock for UC0 is selectable and can be either the external clock input via the TA0IN pin or one of the three internal clocks ϕT1, ϕT4 or ϕT16. The clock setting is specified by the value set in TA01MOD<TA0CLK1:0>.

The input clock for UC1 depends on the operation mode. In 16-bit timer mode, the overflow output from UC0 is used as the input clock. In any mode other than 16-bit timer mode, the input clock is selectable and can either be one of the internal clocks ϕT1, ϕT16 or ϕT256, or the comparator output (the match detection signal) from TMRA0.

For each interval timer the timer operation control register bits TA01RUN<TA0RUN> and TA01RUN<TA1RUN> can be used to stop and clear the up counters and to control their count. A reset clears both up counters, stopping the timers.

(3) Timer registers (TA0REG and TA1REG)

These are 8-bit registers, which can be used to set a time interval. When the value set in the timer register TA0REG or TA1REG matches the value in the corresponding up counter, the comparator match detect signal goes Active. If the value set in the timer register is 00H, the signal goes Active when the up counter overflows.

The TA0REG has a double buffer structure, making a pair with the register buffer.

The setting of the bit TA01RUN<TA0RDE> determines whether TA0REG's double buffer structure is enabled or disabled. It is disabled if <TA0RDE> = "0" and enabled if <TA0RDE> = "1".

When the double buffer is enabled, data is transferred from the register buffer to the timer register when a 2^n overflow occurs in PWM mode, or at the start of the PPG cycle in PPG mode. Hence the double buffer cannot be used in timer mode.

A reset initializes <TA0RDE> to "0", disabling the double buffer. To use the double buffer, write data to the timer register 0, set <TA0RDE> to "1", and write the following data to the register buffer. Figure 3.7.4 show the configuration of TA0REG.

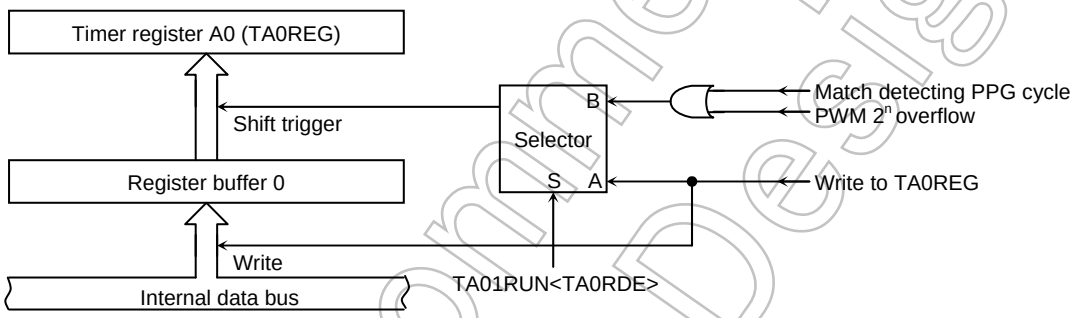

Figure 3.7.4 Configuration of TA0REG

Note: The same memory address is allocated to the timer register and the register buffer. When <TA0RDE> = "0", the same value is written to the register buffer and the timer register; when <TA0RDE> = "1", only the register buffer is written to.

The address of each timer register is as follows.

TA0REG: 001102H TA1REG: 001103H

TA2REG: 00110AH TA3REG: 00110BH

TA4REG: 001112H TA5REG: 001113H

All these registers are write only and cannot be read.

(4) Comparator (CP0, CP1)

The comparator compares the value in an up counter with the value set in a timer register. If they match, the up counter is cleared to "0" and an interrupt signal (INTTA0 or INTTA1) is generated. If timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

(5) Timer flip-flop (TA1FF)

The timer flip-flop (TA1FF) is a flip-flop inverted by the match detect signals (8-bit comparator output) of each interval timer.

Whether inversion is enabled or disabled is determined by the setting of the bit TA1FFCR<TA1FFIE> in the timer flip-flops control register a reset clears the value of TA1FF to "0". Writing "01" or "10" to TA1FFCR<TA1FFC1:0> sets TA1FF to "0" or "1". Writing "00" to these bits inverts the value of TA1FF (this is known as software inversion).

The TA1FF signal is output via the TA1OUT pin (which can also be used as P80).

When this pin is used as the timer output, the timer flip-flop should be set beforehand using the port 8 function register P8CR and P8FC.

3.7.4 Operation in Each Mode

(1) 8-bit timer mode

Both TMRA0 and TMRA1 can be used independently as 8-bit interval timers. When set function and count data, TMRA0 and TMRA1 should be stopped.

1. Generating interrupts at a fixed interval (using TMRA1)

To generate interrupts at constant intervals using TMRA1 (INTTA1), first stop TMRA1 then set the operation mode, input clock and a cycle to TA01MOD and TA1REG register, respectively. Then, enable the interrupt INTTA1 and start TMRA1 counting.

Example: To generate an INTTA1 interrupt every 40 μs at f_C = 40 MHz, set each register as follows:

*Clock state: Clock gear : 1/1(fc)

	MSB 7	6	5	4	3	2	1	LSB 0	
TA01RUN	← –	X	X	X	–	–	0	–	Stop TMRA1 and clear it to "0".
TA01MOD	← 0	0	X	X	0	1	–	–	Select 8-bit timer mode and select φT1 (= (8/fc)s at f_C = 40 MHz) as the input clock.
TA1REG	← 1	1	0	0	1	0	0	0	Set 40 μs ÷ φT1 = 200 = C8H to TAREG.
INTETA01	← X	1	0	1	–	–	–	–	Enable INTTA1 and set it to level 5.
TA01RUN	← –	X	X	X	–	1	1	–	Start TMRA1 counting.

X: Don't care, –: No change

Select the input clock using Table 3.7.3.

Table 3.7.3 Selecting Interrupt Interval and the Input Clock Using 8-Bit Timer

Input Clock	Interrupt Interval (at f_C = 40 MHz)	Resolution
φT1 (8/fC)	0.2 μs to 51.2 μs	0.2 μs
φT4 (32/fC)	0.8 μs to 204.8 μs	0.8 μs
φT16 (128/fC)	3.2 μs to 819.2μs	3.2 μs
φT256 (2048/fC)	51.2 μs to 13.11 ms	51.2 μs

Note: The input clocks for TMRA0 and TMRA1 differ as follows:

TMRA0: Uses TMRA0 input (TA0IN) and can be selected from φT1, φT4 or φT16

TMRA1: Matches output of TMRA0 (TA0TRG) and can be selected from φT1, φT16, φT256

2. Generating a 50 % duty ratio square wave pulse

The state of the timer flip-flop (TA1FF) is inverted at constant intervals and its status output via the timer output pin (TA1OUT).

Example: To output a 1.2-μs square wave pulse from the TA1OUT pin at f_C = 40 MHz, use the following procedure to make the appropriate register settings. This example uses TMRA1; however, either TMRA0 or TMRA1 may be used.

*Clock state: Clock gear : 1/1(fc)

		7	6	5	4	3	2	1	0	
TA01RUN	←	–	X	X	X	–	–	0	–	Stop TMRA1 and clear it to "0".
TA01MOD	←	0	0	X	X	0	1	–	–	Select 8-bit timer mode and select φT1 (= (8/fc)s at f_C = 40 MHz) as the input clock.
TA1REG	←	0	0	0	0	0	0	1	1	Set the timer register to 1.2 μs ÷ φT1 ÷ 2 = 3
TA1FFCR	←	X	X	X	X	1	0	1	1	Clear TA1FF to "0" and set it to invert on the match detect signal from TMRA1.
P8FC	←	X	X	X	X	–	X	–	1	Set P80 to function as the TA1OUT pin.
TA01RUN	←	–	X	X	X	–	1	1	–	Start TMRA1 counting.

X: Don't care, –: No change

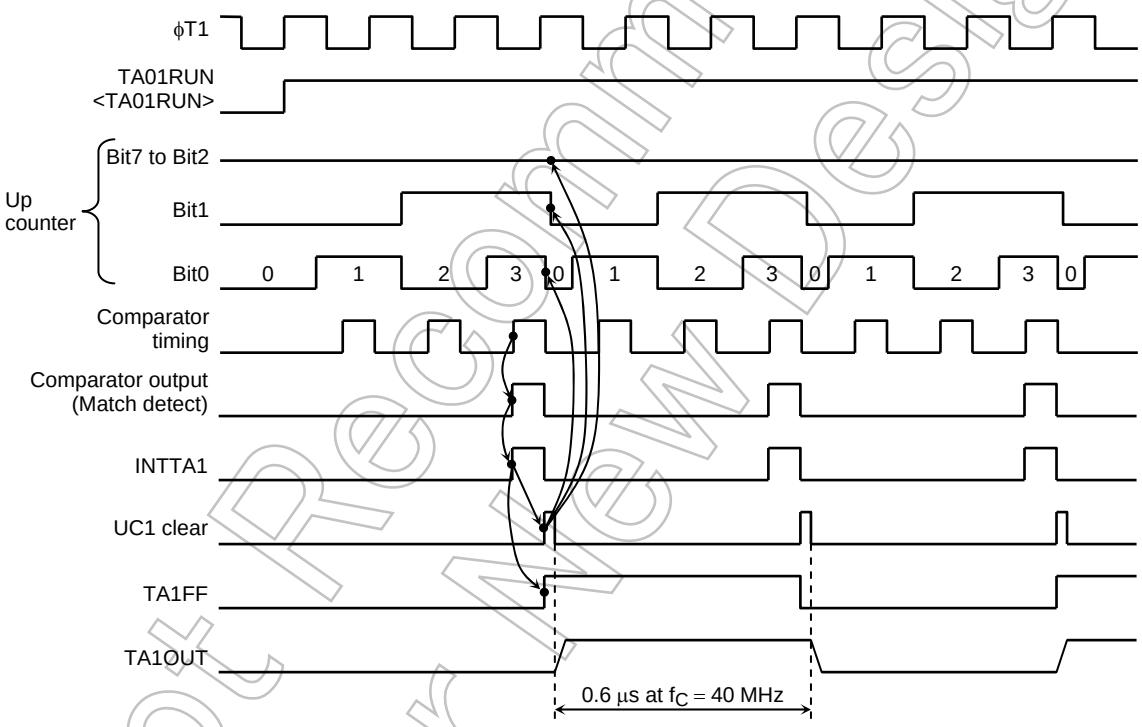

Figure 3.7.14 Square Wave Output Timing Chart (50 % Duty)

3. Making TMRA1 count up on the match signal from the TMRA0 comparator

Select 8-bit timer mode and set the comparator output from TMRA0 to be the input clock to TMRA1.

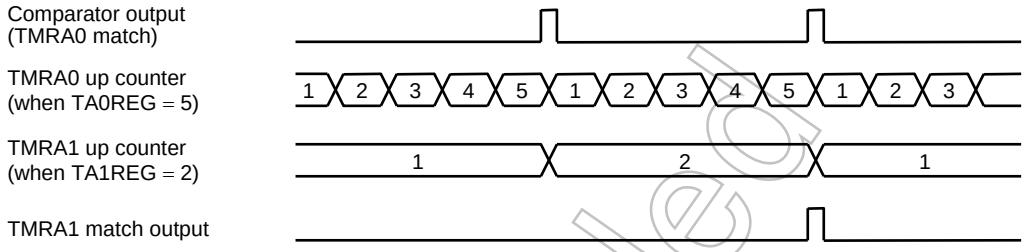

Figure 3.7.15 TMRA1 Count Up on Signal from TMRA0

(2) 16-bit timer mode

A 16-bit interval timer is configured by pairing the two 8-bit timers TMRA0 and TMRA1.

To make a 16-bit interval timer in which TMRA0 and TMRA1 are cascaded together, set TA01MOD<TA01M1:0> to "01".

In 16-bit timer mode, the overflow output from TMRA0 is used as the input clock for TMRA1, regardless of the value set in TA01MOD<TA01CLK1:0>. Table 3.7.2 shows the relationship between the timer (interrupt) cycle and the input clock selection.

To set the timer interrupt interval, set the lower eight bits in timer register TA0REG and the upper eight bits in TA1REG. Be sure to set TA0REG first (as entering data in TA0REG temporarily disables the compare, while entering data in TA1REG starts the compare).

Setting example: To generate an INTTA1 interrupt every 0.2 s at f_C = 40 MHz, set the timer registers TA0REG and TA1REG as follows:
*Clock state: Clock gear : 1/1(fc)

If ϕT16 (=(128/fc)s at f_C = 40 MHz) is used as the input clock for counting, set the following value in the registers:

0.2 s ÷ (128/fc)s = 62500 = F424H; e.g. set TA1REG to F4H and TA0REG to 24H.

The comparator match signal is output from TMRA0 each time the up counter UC0 matches TA0REG, though the up counter UC0 is not cleared.

In the case of the TMRA1 comparator, the match detect signal is output on each comparator pulse on which the values in the up counter UC1 and TA1REG match. When the match detect signal is output simultaneously from both the comparator TMRA0 and TMRA1, the up counters UC0 and UC1 are cleared to "0" and the interrupt INTTA1 is generated. Also, if inversion is enabled, the value of the timer flip-flop TA1FF is inverted.

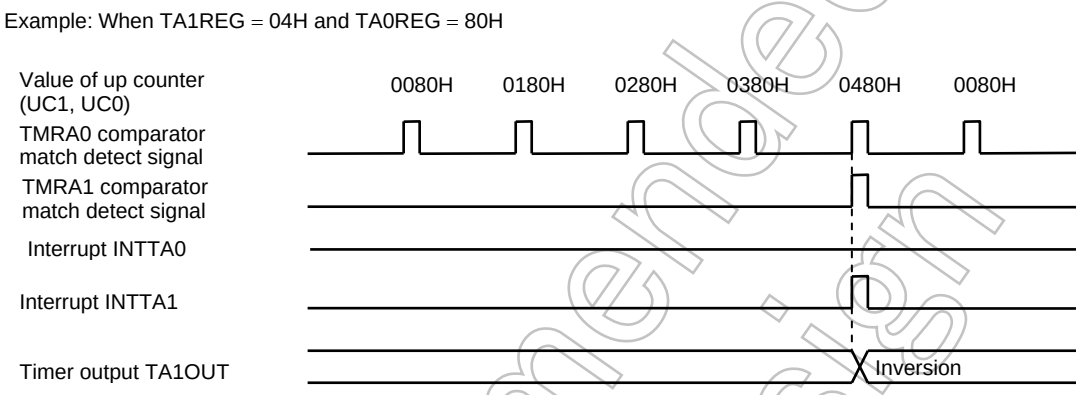

Figure 3.7.16 Timer Output by 16-Bit Timer Mode

(3) 8-bit PPG (Programmable pulse generation) output mode

Square wave pulses can be generated at any frequency and duty ratio by TMRA0. The output pulses may be active low or active high. In this mode TMRA1 cannot be used.

TMRA0 outputs pulses on the TA1OUT pin (which can also be used as P80).

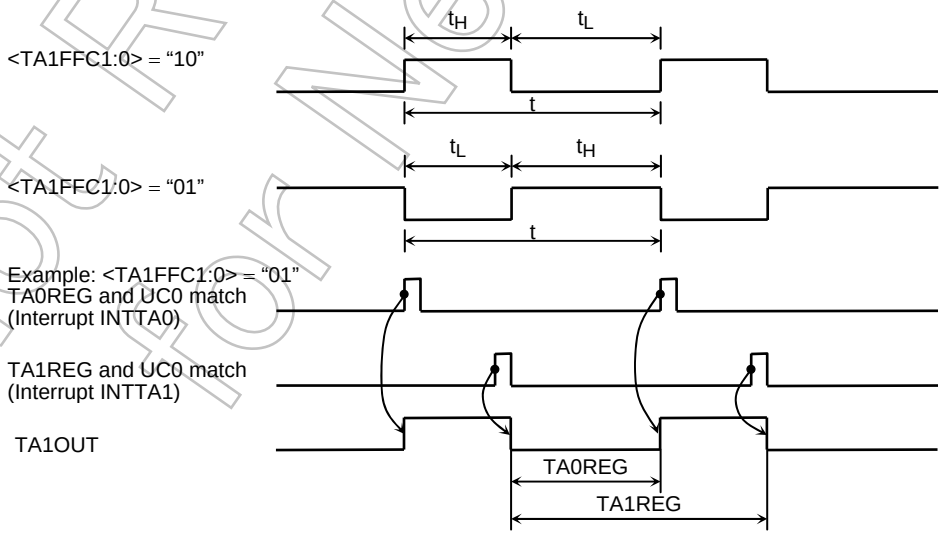

Figure 3.7.17 8-Bit PPG Output Waveforms

In this mode a programmable square wave is generated by inverting the timer output each time the 8-bit up counter (UC0) matches the value in one of the timer registers TA0REG or TA1REG.

The value set in TA0REG must be smaller than the value set in TA1REG.

Although the up counter for TMRA1 (UC1) is not used in this mode,

TA01RUN<TA1RUN> should be set to "1" so that UC1 is set for counting.

Figure 3.7.18 shows a block diagram representing this mode.

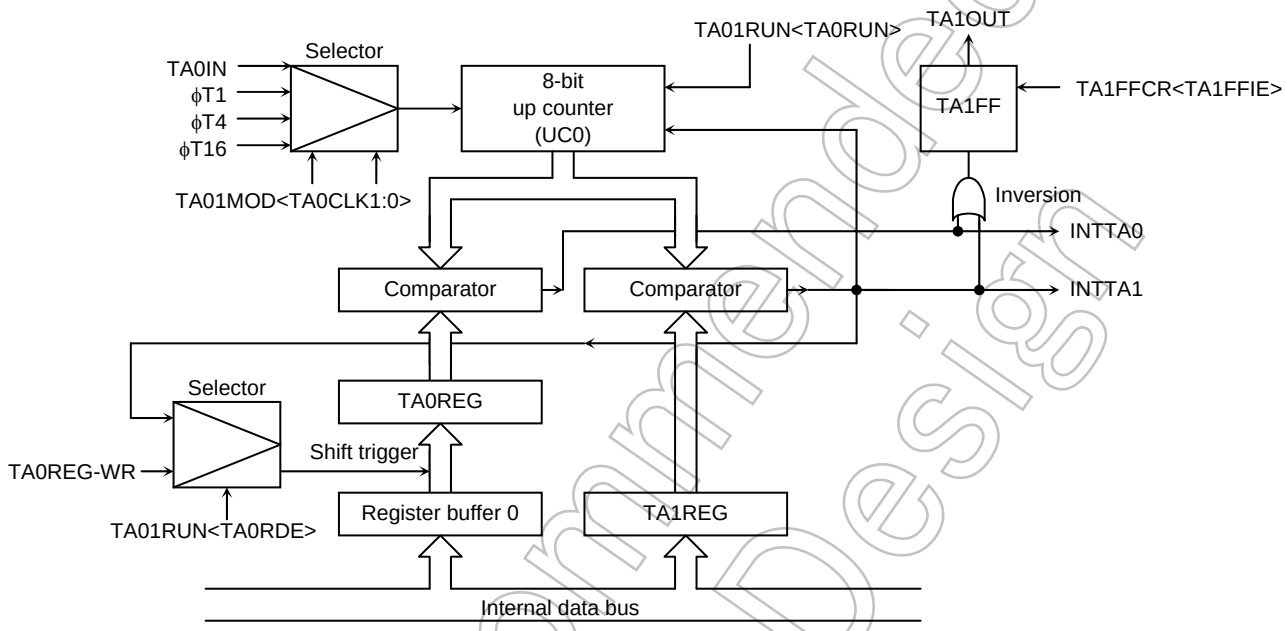

Figure 3.7.18 Block Diagram of 8-Bit PPG Output Mode

If the TA0REG double buffer is enabled in this mode, the value of the register buffer will be shifted into TA0REG each time TA1REG matches UC0.

Use of the double buffer facilitates the handling of low duty waves (when duty is varied).

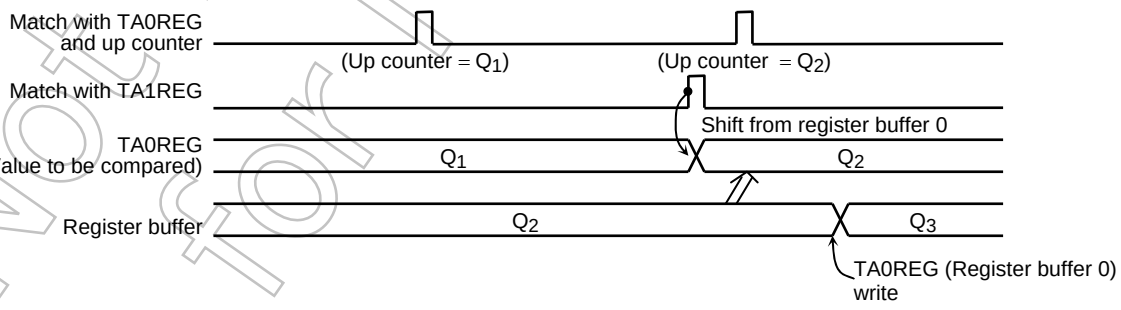

Figure 3.7.19 Operation of Register Buffer 0

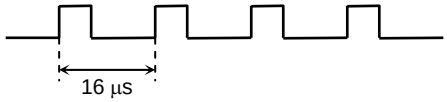
Example: To generate 1/4 duty 62.5 kHz pulses (at f_C = 40 MHz)



*Clock state: Clock gear : 1/1(fc)

Calculate the value that should be set in the timer register.
To obtain a frequency of 62.5 kHz, the pulse cycle t should be:

t = 1/62.5 kHz = 16 μs

ϕT1 (= (8/fc)s @f_C = 40 MHz);

16 μs ÷ (8/fc)s = 80

Therefore set TA1REG = 80 = 50H

The duty is to be set to 1/4: t × 1/4 = 16 μs × 1/4 = 4 μs

4 μs ÷ (8/fc)s = 20

Therefore, set TA0REG = 20 = 14H

		7	6	5	4	3	2	1	0

X: Don't care, –: No change

(4) 8-bit PWM output mode

This mode is only valid for TMRA0. In this mode, a PWM pulse with the maximum resolution of 8 bits can be output.

When TMRA0 is used the PWM pulse is output on the TA1OUT pin (which is also used as P80). TMRA1 can also be used as an 8-bit timer.

The timer output is inverted when the up counter (UC0) matches the value set in the timer register TA0REG or when 2^n counter overflow occurs (n = 6, 7 or 8 as specified by TA01MOD<PWM01:00>). The up counter UC0 is cleared when 2^n counter overflow occurs. The following conditions must be satisfied before this PWM mode can be used.

Value set in TA0REG < value set for 2^n counter overflow

Value set in TA0REG ≠ "0"

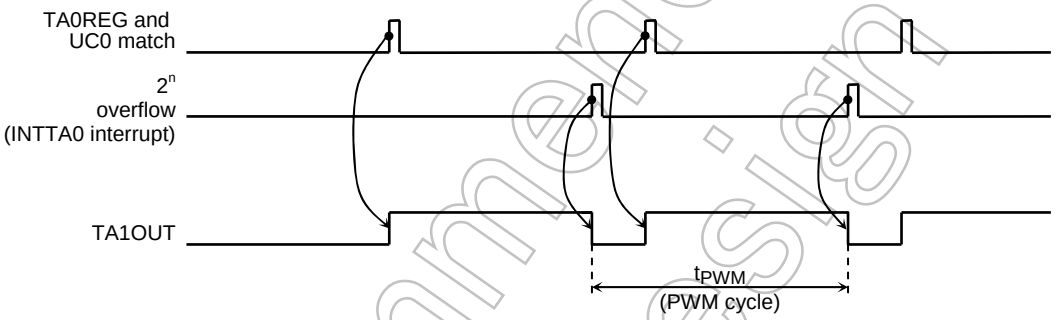

Figure 3.7.20 8-Bit PWM Waveforms

Figure 3.7.21 shows a block diagram representing this mode.

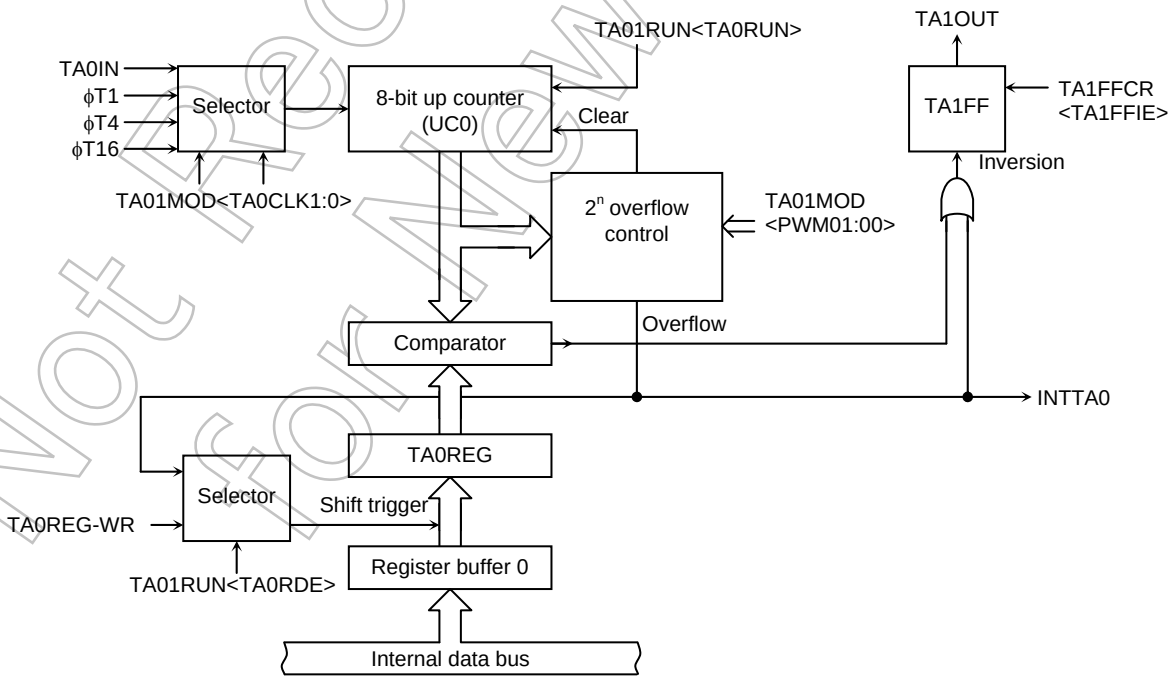

Figure 3.7.21 Block Diagram of 8-Bit PWM Mode

In this mode the value of the register buffer will be shifted into TA0REG if 2^n overflow is detected when the TA0REG double buffer is enabled.

Use of the double buffer facilitates the handling of low duty ratio waves.

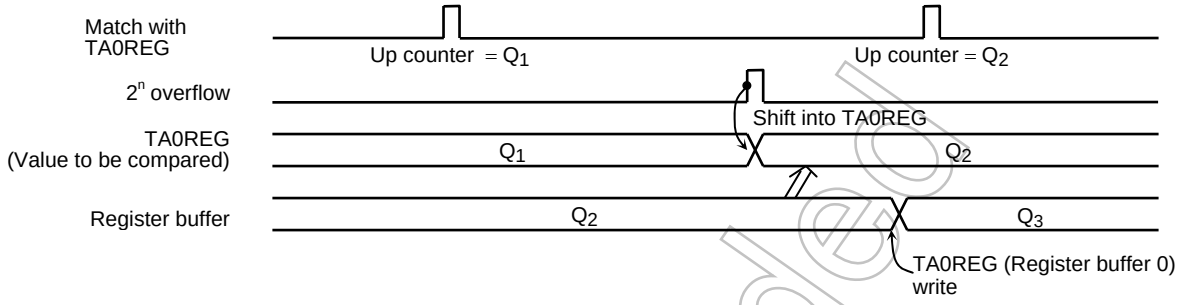

Figure 3.7.22 Register Buffer Operation

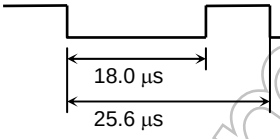
Example: To output the following PWM waves on the TA1OUT pin (at f_C = 40 MHz).



*Clock state: Clock gear : 1/1(fc)

To achieve a 25.6-μs PWM cycle by setting ϕT1 (= (8/fc)s at f_C = 40 MHz):
25.6 μs ÷ (8/fc)s = 128 = 2^n
Therefore n should be set to 7.
Since the low level period is 18.0 μs when ϕT1 = (8/fc)s,
set the following value for TREG0:

18.0 μs ÷ (8/fc)s = 90 = 5AH

	MSB 7	6	5	4	3	2	1	LSB 0	
TA01RUN	← –	X	X	X	–	–	–	0	Stop TMRA0 and clear it to "0"

3.8 16-Bit Timer/Event Counters (TMRB0)

The TMP92CY23/CD23A incorporates two multifunctional 16-bit timer/event counter (TMRB0 and TMRB1) which has the following operation modes:

- 16-bit interval timer
- 16-bit event counter
- 16-bit programmable pulse generation (PPG)

Can be used following operation modes by capture function.

- Frequency measurement mode
- Pulse width measurement mode
- Time differential measurement mode

Figure 3.8.1 and Figure 3.8.2 show block diagram of TMRB0 and TMRB1.

The timer/event counter consists of a 16-bit up counter, two 16-bit timer registers (one of them with a double buffer structure), two 16-bit capture register, two comparators, a capture input controller, a timer flip-flop and a control circuit.

The timer/event counter is controlled by a 11-byte SFR. Each channel(TMRB0,TMRB1) operate independently.

In this section, the explanation describes only for TMRB1 because each channel is identical operation except for the difference as follows;

Table 3.8.1 Pins and SFR of TMRB

3.8.1 Block Diagrams

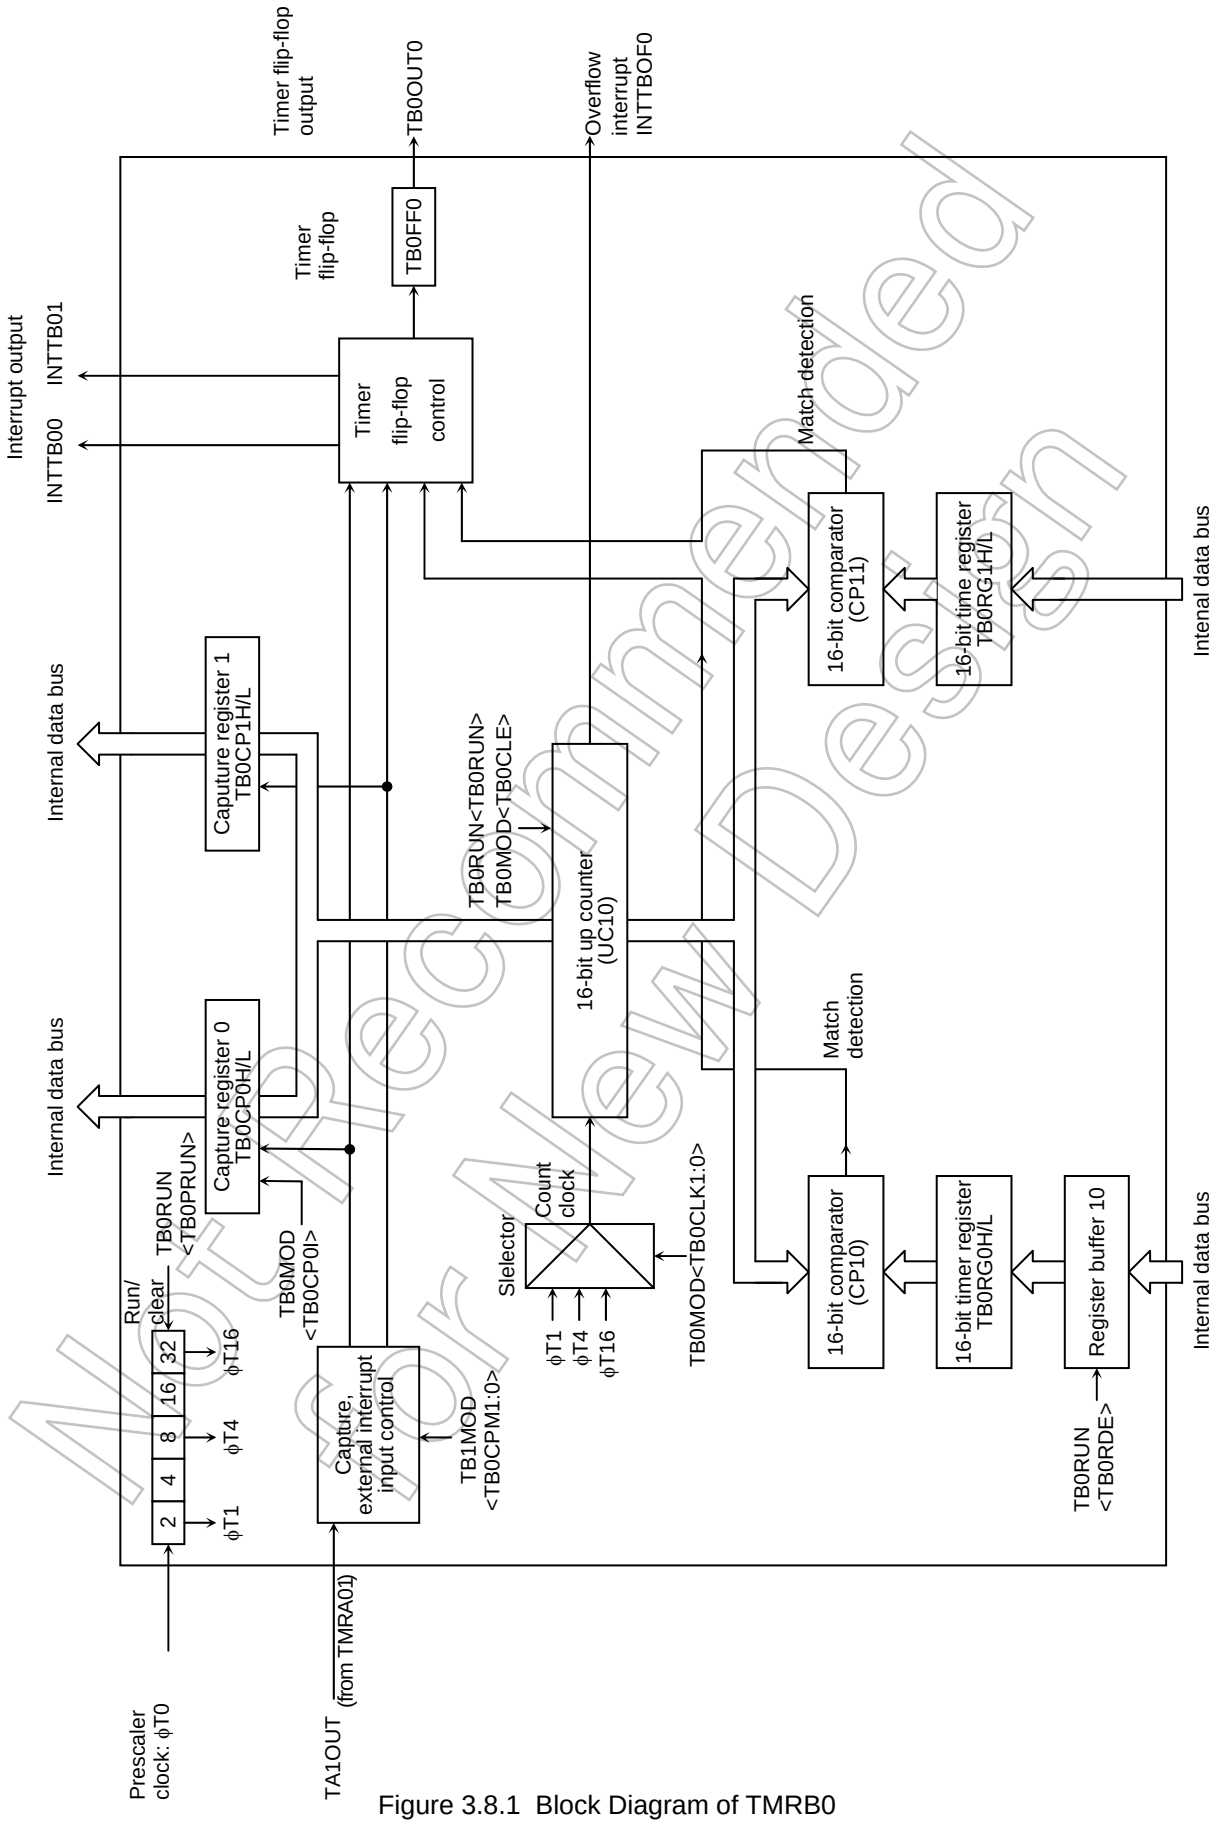

Figure 3.8.1 Block Diagram of TMRB0

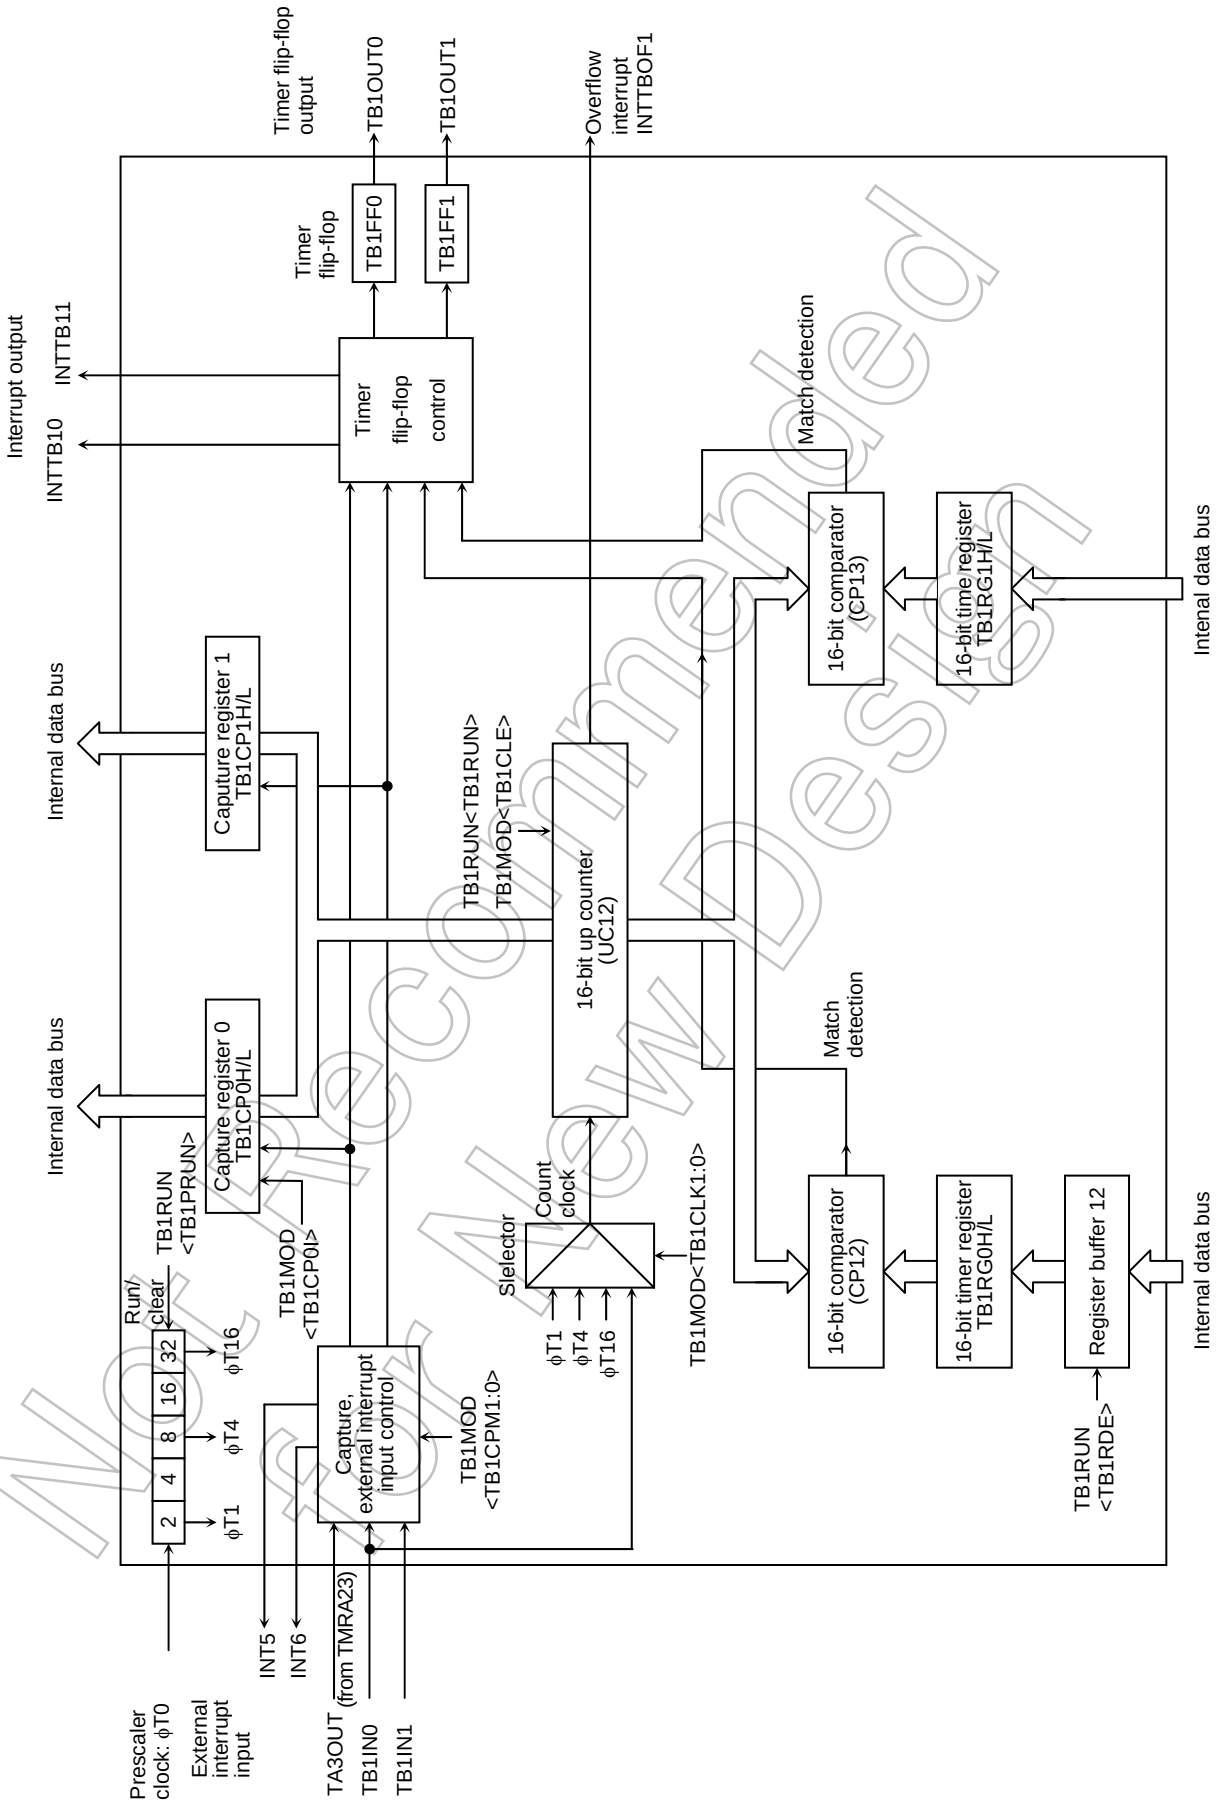

Figure 3.8.2 Block Diagram of TMRB1

3.8.2 Operation of Each Block

(1) Prescaler

The 5-bit prescaler generates the source clock for TMRB1. The prescaler clock (ϕT0) is a divided clock (divided by 4) from the f_{FPH}.

This prescaler can be started or stopped using TB1RUN<TB1PRUN>. Counting starts when <TB0PRUN> is set to "1"; the prescaler is cleared to "0" and stops operation when <TB0PRUN> is cleared to "0".

Table 3.8.2 Prescaler Clock Resolution

Gear Value SYSCR1 <GEAR2:0>	System clock SYSCR1 <SYSCK>	–	Timer counter input clock TMRB prescaler TBxMOD<TBxCLK1:0>		
			ϕT1(1/2)	ϕT4(1/8)	ϕT16(1/32)
–	1 (fs)	1/4	fs/8	fs/32	fs/128
000 (1/1)	0 (fc)		fc/8	fc/32	fc/128
001 (1/2)			fc/16	fc/64	fc/256
010 (1/4)			fc/64	fc/128	fc/512
011 (1/8)			fc/64	fc/256	fc/1024
100 (1/16)			fc/128	fc/512	fc/2048

(2) Up counter (UC12)

UC12 is a 16-bit binary counter which counts up pulses input from the clock specified by TB0MOD<TB0CLK1:0>.

Any one of the prescaler internal clocks ϕT1, ϕT4 and ϕT16 can be selected as the input clock. Counting or stopping and clearing of the counter is controlled by TB1RUN<TB1RUN>. TMRB0 cannot choose an external clock as an input clock (there is no external clock input terminal).

When clearing is enabled, the up counter UC12 will be cleared to 0 each time its value matches the value in the timer register TB1RG1H/L. If clearing is disabled, the counter operates as a free-running counter. Clearing can be enabled or disabled using TB1MOD<TB1CLE>.

A timer overflow interrupt (INTTBOF1) is generated when UC12 overflow occurs.

(3) Timer registers (TB1RG0H/L and TB1RG1H/L)

These 16-bit registers are used to set the interval time. When the value in the up counter UC12 matches the value set in this timer register, the comparator match detect signal will go active.

Setting data for both Upper and Lower timer registers is always needed. For example, either using a 2-byte data transfer instruction or using a 1-byte data transfer instruction twice for the lower 8 bits and upper 8 bits in order.

The TB1RG0H/L timer register has a double-buffer structure, which is paired with a register buffer. The value set in TB1RUN<TB1RDE> determines whether the double-buffer structure is enabled or disabled: it is disabled when <TB1RDE> = "0", and enabled when <TB1RDE> = "1".

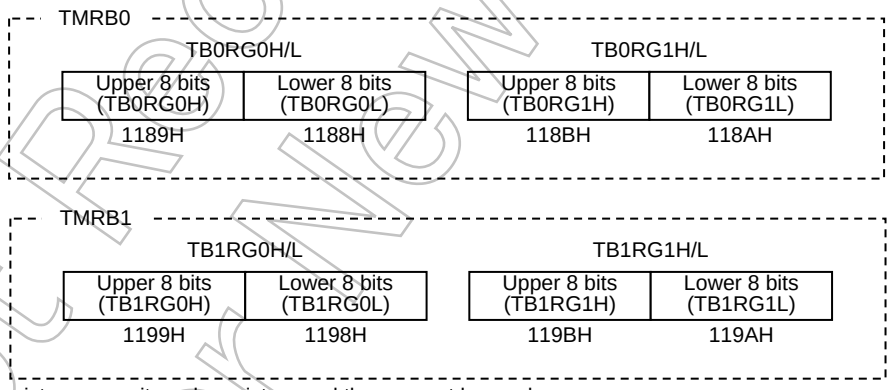
When the double buffer is enabled, data is transferred from the register buffer to the timer register when the values in the up counter (UC12) and the timer register TB1RG1H/L match.

After a reset, TB1RG0H/L and TB1RG1H/L are undefined. If the 16-bit timer is to be used after a reset, data should be written to it beforehand.

On a reset <TB1RDE> is initialized to "0", disabling the double buffer. To use the double buffer, write data to the timer register, set <TB1RDE> to "1", then write data to the register buffer as shown below.

TB1RG0H/L and the register buffer both have the same memory addresses (1188H and 1189H) allocated to them. If <TB1RDE> = "0", the value is written to both the timer register and the register buffer. If <TB1RDE> = "1", the value is written to the register buffer only.

The addresses of the timer registers are as follows:



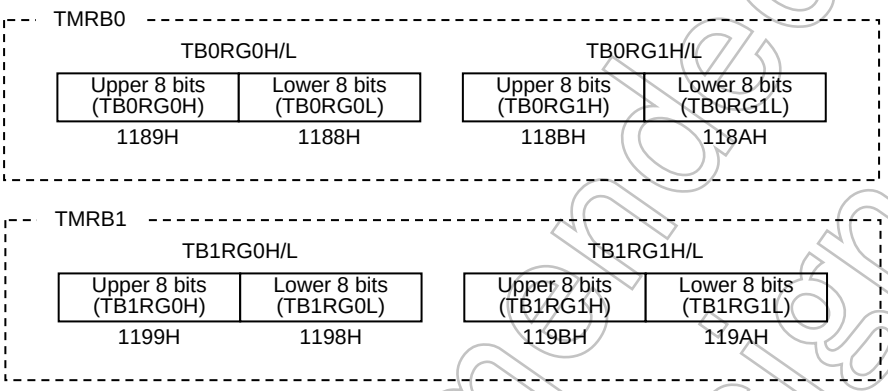
The timer registers are write-only registers and thus cannot be read.

(4) Capture registers (TB1CP0H/L and TB1CP1H/L)

These 16-bit registers are used to latch the values in the up counters UC12.

All 16 bits of data in the capture registers should be read. For example, using a 2-byte data load instruction or two 1-byte data load instructions twice for lower 8 bits and upper 8 bits in order.

The addresses of the capture registers are as follows:



The capture registers are read-only registers and thus cannot be written to.

(5) Capture input control

This circuit controls the timing to latch the value of the up counter UC12 into TB1CP0H/L and TB1CP1H/L.

Interrupt timing of capture register and selection edge of external interrupt are set by TB1MOD<TB1CPM1:0>. (TMRB0 does not include the selection edge of external interrupt.)

The value in the up counter can be loaded into a capture register by software. Whenever 0 is programmed to TB1MOD<TB1CP0I>, the current value in the up counter is loaded into capture register TB1CP0H/L. It is necessary to keep the prescaler in run mode (e.g., TB1RUN<TB1PRUN> must be held at a value of 1).

(6) Comparators (CP12, CP13)

CP12 is 16-bit comparators which compare the value in the up counter UC12 with the value set in TB1RG0H/L or TB1RG1H/L respectively, in order to detect a match. If a match is detected, the comparator generates an interrupt (INTTB10 or INTTB11 respectively).

(7) Timer flip-flops (TB1FF0 and TB1FF1)

These flip-flops are inverted by the match detect signals from the comparators and the latch signals to the capture registers. Inversion can be enabled and disabled for each element using TB1FFCR<TB1C0T1, TB1E1T1 and TB1E0T1>.

After a reset the value of TB1FF0 is undefined. If "00" is programmed to TB1FFCR <TB1FF0C1:0> or <TB1FF1C1:0>, TB1FF0 will be inverted. If "01" is programmed to the capture registers, the value of TB1FF0 will be set to "1". If "10" is programmed to the capture registers, the value of TB1FF0 will be cleared to "0".

The values of TB1FF0 and TB1FF1 can be output via the timer output pin TB1OUT0 (which is shared with PD3), TB1OUT1 (which is shard with PD4). The timer output pin of TMRB0 is one pin (TB0OUT0: which is shard with PD0). Timer output should be specified using the port D function register.

Figure 3.8.9 The Registers for TMRB

3.8.4 Operation in Each Mode

(1) 16-bit interval timer mode

Generating interrupts at fixed intervals in this example, the interval time is set the timer register TB1RG1H/L to generate the interrupt INTTB11.

		7	6	5	4	3	2	1	0	
TB1RUN	←	0	0	X	X	–	0	X	0	Stop TMRB1.
INTETB1	←	X	1	0	0	X	0	0	0	Enable INTTB11 and set interrupt level 4. Disable INTTB10.
TB1FFCR	←	1	1	0	0	0	0	1	1	Disable the trigger.
TB1MOD	←	0	0	1	0	0	1	*	*	Select internal clock for input and disable the capture function.
				(** = 01, 10, 11)						
TB1RG1H/L	←	*	*	*	*	*	*	*	*	Set the interval time (16 bits).
		*	*	*	*	*	*	*	*	
TB1RUN	←	0	0	X	X	–	1	X	1	Start TMRB1.

X: Don't care, –: No change

(2) 16-bit event counter mode

In 16-bit timer mode as described in above, the timer can be used as an event counter by selecting the external clock (TB1IN0 pin input) as the input clock.

Up counter counting up by rising edge of TB1IN0 pin input. And execution software capture and reading capture value enable reading count value.

		7	6	5	4	3	2	1	0	
TB1RUN	←	0	0	X	X	–	0	X	0	Stop TMRB1.
PDCR	←	X	X	X	X	–	–	0	–	Set PD1 to TB1IN0 input mode.
PDFC2	←	X	X	X	X	–	–	0	X	
PDFC	←	X	X	X	X	–	–	1	–	
INTETB1	←	X	1	0	0	X	0	0	0	Set INTTB11 to enable (Interrupt level4). Set INTTB10 to disable.
TB1FFCR	←	1	1	0	0	0	0	1	1	Set trigger to disable.
TB1MOD	←	0	0	1	0	0	1	0	0	Set input clock to TB1IN0 pin input.
TB1RG1H/L	←	*	*	*	*	*	*	*	*	Set number of count. (16 bits)
		*	*	*	*	*	*	*	*	
TB1RUN	←	0	0	X	X	–	1	X	1	Start TMRB1.

X: Don't care, –: No change

Note: When used as an event counter, set the prescaler to "RUN" (TB1RUN<TB1PRUN> = "1").

(3) 16-bit programmable pulse generation (PPG) output mode

Square wave pulses can be generated at any frequency and duty ratio. The output pulse may be either low active or high active.

The PPG mode is obtained by inversion of the timer flip-flop TB1FF0 that is enabled by the match of the up counter UC12 with timer register TB1RG0H/L or TB1RG1H/L and is output to TB1OUT0. In this mode the following conditions must be satisfied.

(Value set in TB1RG0H/L) < (Value set in TB1RG1H/L)

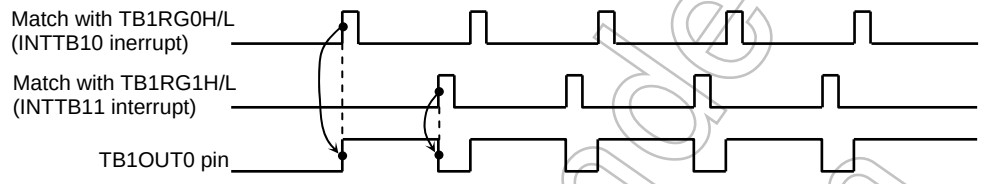

Figure 3.8.10 Programmable Pulse Generation (PPG) Output Waveforms

When the TB1RG0H/L double buffer is enabled in this mode, the value of register buffer 12 will be shifted into TB1RG0H/L at match with TB1RG1H/L. This feature facilitates the handling of low duty waves.

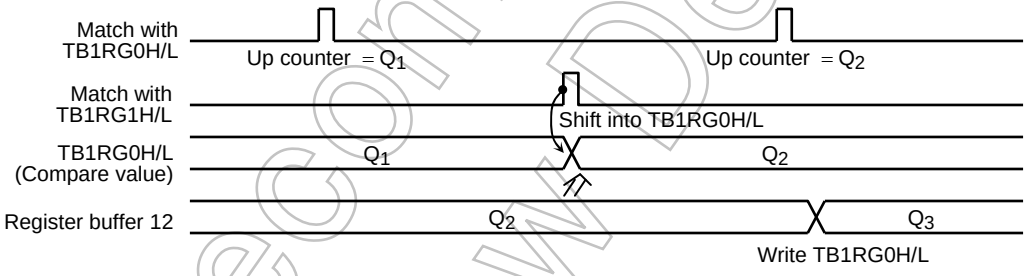

Figure 3.8.11 Operation of Register Buffer

The following block diagram illustrates this mode.

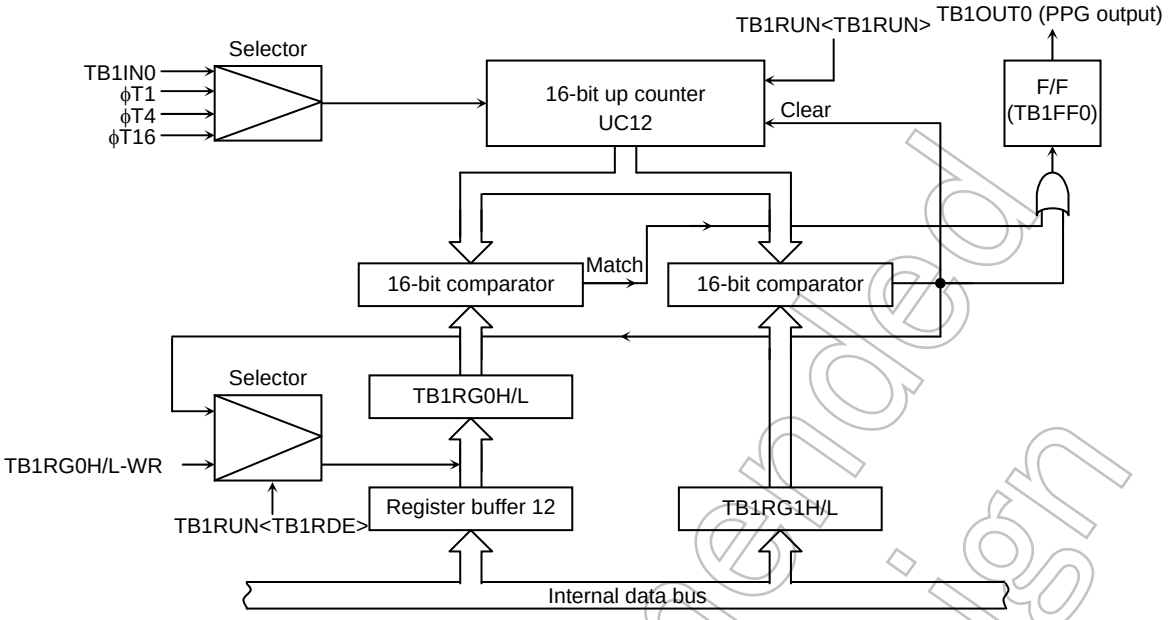

Figure 3.8.12 Block Diagram of 16-Bit Mode

The following example shows how to set 16-bit PPG output mode:

		7	6	5	4	3	2	1	0	
TB1RUN	←	0	0	X	X	–	0	X	0	Disable the TB1RG0H/L double buffer and stop TMRB0.
TB1RG0H/L	←	*	*	*	*	*	*	*	*	Set the duty ratio (16 bits).
		*	*	*	*	*	*	*	*	
TB1RG1H/L	←	*	*	*	*	*	*	*	*	Set the frequency (16 bits).
		*	*	*	*	*	*	*	*	
TB1RUN	←	1	0	X	X	–	0	X	0	Enable the TB1RG0H/L double buffer. (The duty and frequency are changed on an INTTB11 interrupt.)
TB1FFCR	←	1	1	0	0	1	1	1	0	Set the mode to invert TB0FF0 at the match with TB1RG0H/L, TB1RG1H/L. Clear TB1FF0H/L to "0".
TB1MOD	←	0	0	1	0	0	1	*	*	Select the internal clock as the input clock and disable the capture function.
		(** = 01, 10, 11)								
PDFC2	←	X	X	X	–	0	–	–	X	
PDFC		X	X	X	–	1	–	–	–	Set PD3 to function as TB1OUT0.
PDCR	←	X	X	X	–	1	–	X	–	
TB1RUN	←	1	0	X	X	–	1	X	1	Start TMRB1.

X: Don't care, –: No change

(4) Capture function examples

Used capture function, they can be applicable in many ways, for example:

1. One-shot pulse output from external trigger pulse
2. Frequency measurement
3. Pulse width measurement
4. Measurement of difference time

1. One-shot pulse output from external trigger pulse

Set the up counter UC12 in free-running mode with the internal input clock, input the external trigger pulse from TB1IN0 pin, and load the value of up counter into capture register TB1CP0H/L at the rise edge of external trigger pulse.

When the interrupt INT5 is generated at the rise edge of external trigger pulse, set the TB1CP0H/L value (c) plus a delay time (d) to TB1RG0H/L (= c + d), and set the above set value (c + d) plus a one-shot width (p) to TB1RG1H/L (= c + d + p). And, set "11" to timer flip-flop control register TB1FFCR<TB1E1T1, TB1E0T1>. Set to trigger enable for be inverted timer flip-flop TB1FF0 by UC0 matching with TB1RG0H/L and with TB1RG1H/L. When interrupt INTTB11 occurs, this inversion will be disabled after one-shot pulse is output.

The (c), (d), and (p) correspond to c, d, and p in Figure 3.8.13.

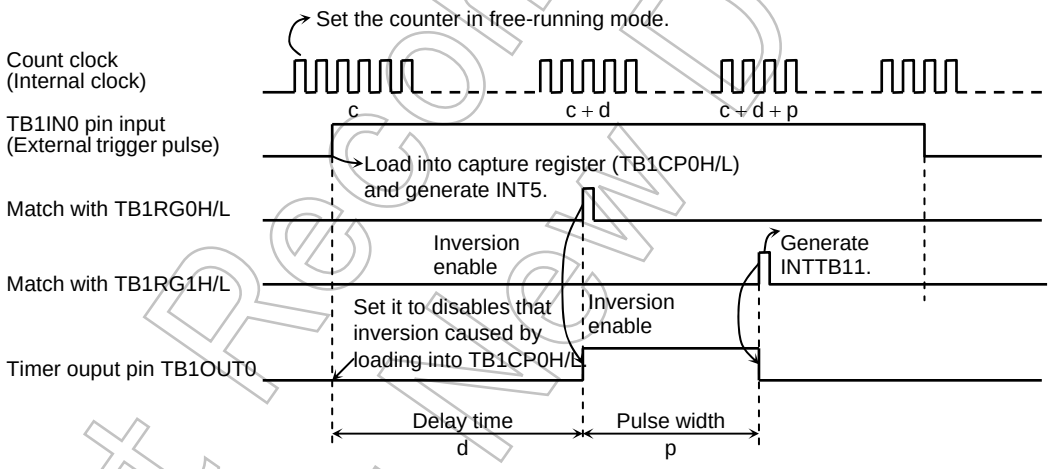

Figure 3.8.13 One-shot Pulse Output (with delay)

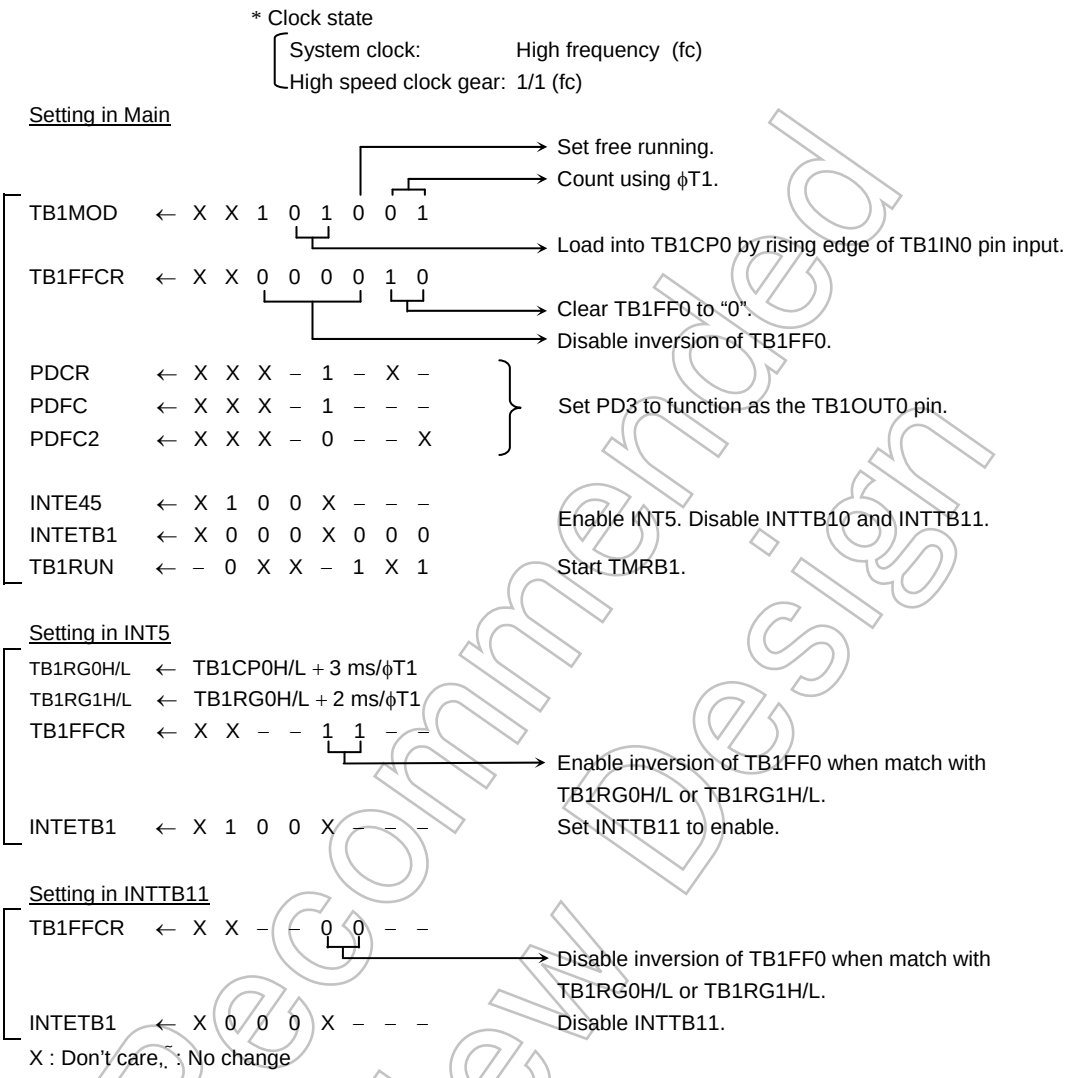
Example: To output a 2 [ms] one-shot pulse with a 3 [ms] delay to the external trigger pulse via the TB1IN0 pin.



When delay time is unnecessary, invert timer flip-flop TB1FF0 when up counter value is loaded into capture register (TB1CP0H/L), and set the TB1CP0H/L value (c) plus the one-shot pulse width (p) to TB0RG1H/L when the interrupt INT5 occurs. The TB1FF0 inversion should be enable when the up counter (UC12) value matches TB1RG1H/L, and disabled when generating the interrupt INTTB11.

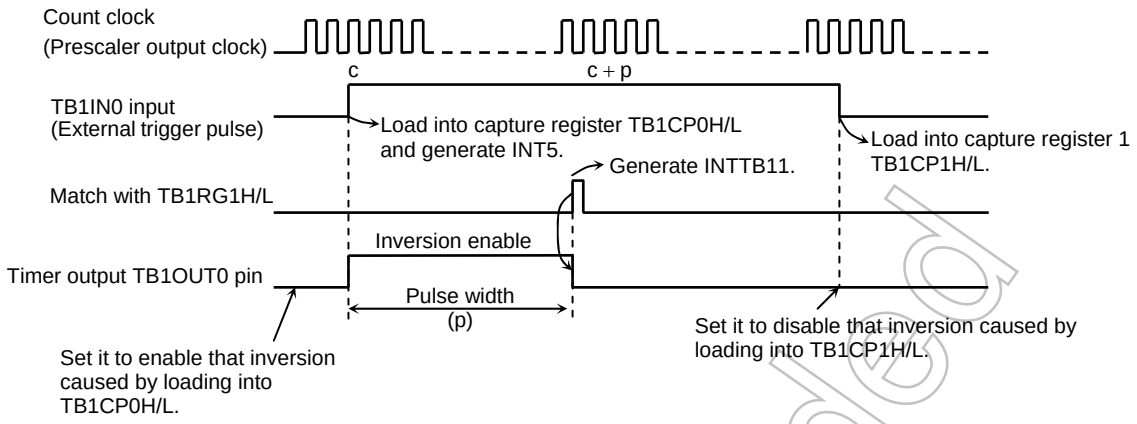


Figure 3.8.14 One-shot Pulse Output (without delay)

2. Frequency measurement

The frequency of the external clock can be measured in this mode. Frequency is measured by the 8-bit timers TMRA23 and the 16-bit timer/event counter.

TMRA23 is used to setting of measurement time by inversion TA3FF.

Counter clock in TMRB1 select TB1IN0 pin input, and count by external clock input. Set to TB1MOD<TB1CPM1:0> = "11". The value of the up counter (UC12) is loaded into the capture register TB1CP0H/L at the rise edge of the timer flip-flop TA3FF of 8-bit timers (TMRA23), and into TB0CP1H/L at its fall edge.

The frequency is calculated by difference between the loaded values in TB1CP0H/L and TB1CP1H/L when the interrupt (INTTA2 or INTTA3) is generates by either 8-bit timer.

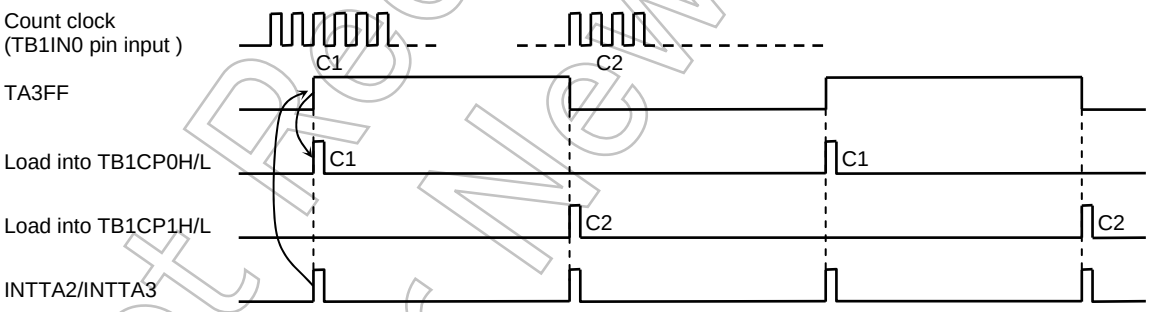

Figure 3.8.15 Frequency Measurement

For example, if the value for the level 1 width of TA3FF of the 8-bit timer is set to 0.5 s and the difference between the values in TB1CP0H/L and TB1CP1H/L is 100, the frequency is 100 ÷ 0.5 s = 200 Hz.

3. Pulse width measurement

This mode allows measuring the high level width of an external pulse. While keeping the 16-bit timer/event counter counting (Free running) with the prescaler output clock input, external pulse is input through the TB1IN0 pin. Then the capture function is used to load the UC12 values into TB1CP0H/L and TB1CP1H/L at the rising edge and falling edge of the external trigger pulse respectively. The interrupt INT5 occurs at the falling edge of TB1IN0.

The pulse width is obtained from the difference between the values of TB1CP0H/L and TB1CP1H/L and the internal clock cycle.

For example, if the prescaler output clock is 0.8 μs and the difference between TB1CP0H/L and TB1CP1H/L is 100, the pulse width will be 100 × 0.8 μs = 80 μs.

Additionally, the pulse width that is over the UC12 maximum count time specified by the clock source can be measured by changing software.

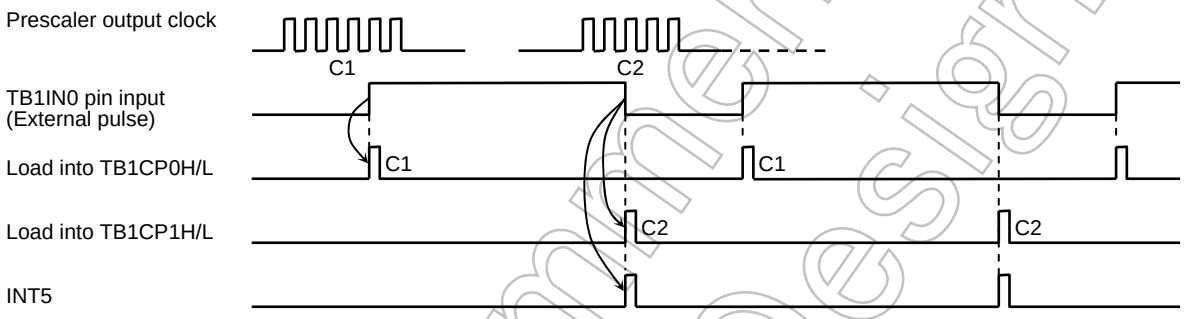

Figure 3.8.16 Pulse Width Measurement

Note: Pulse Width measure by setting "10" to TB1MOD<TB1CPM1:0>. The external interrupt INT5 is generated in timing of falling edge of TB1IN0 input. In other modes, it is generated in timing of rising edge of TB1IN0 input.

The width of low level can be measured from the difference between the first C2 and the second C1 at the second INT5 interrupt.

4. Measurement of difference time

This mode is used to measure the difference in time between the rising edges of external pulses input through TB1IN0 and TB1IN1.

Keep the 16-bit timer/event counter (TMRB1) counting (Free running) with the prescaler output clock, and load the UC12 value into TB1CP0H/L at the rising edge of the input pulse to TB1IN0. Then the interrupt INT5 is generated.

Similarly, the UC12 value is loaded into TB1CP1H/L at the rising edge of the input pulse to TB1IN1, generating the interrupt INT6.

The time difference between these pulses can be obtained by multiplying the value subtracted TB1CP0H/L from TB1CP1H/L and the internal clock cycle together at which loading the UC12 value into TB1CP0H/L and TB1CP1H/L has been done.

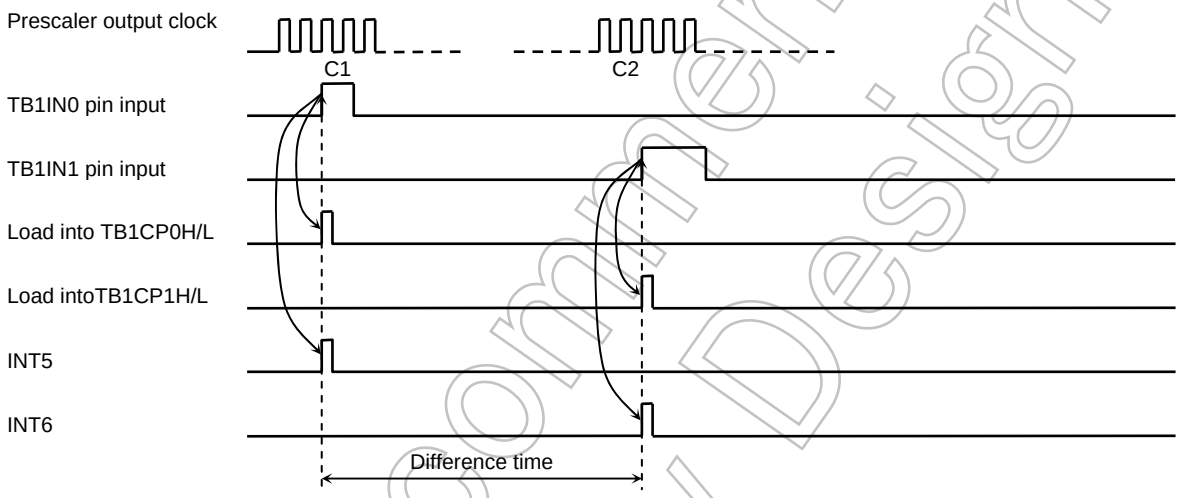

Figure 3.8.17 Measurement of Difference Time

3.9 Serial Channels

The TMP92CY23/CD23A includes 3 serial I/O channels. Each channel is called SIO0, SIO1 and SIO2. For each channel either UART mode (asynchronous transmission) or I/O interface mode (synchronous transmission) can be selected.

- I/O interface mode
  - Mode 0: For transmitting and receiving I/O data using the synchronizing signal SCLK for extending I/O.
- UART mode
  - Mode 1: 7-bit data
  - Mode 2: 8-bit data
  - Mode 3: 9-bit data

In mode 1 and mode 2 a parity bit can be added. Mode 3 has a wakeup function for making the master controller start slave controllers via a serial link (a multi controller system).

Figure 3.9.2, Figure 3.9.3 and Figure 3.9.4 are block diagrams for each channel.

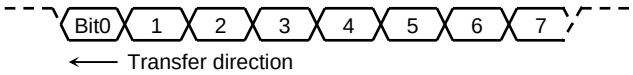
Each channel can be used independently.

Each channel operates in the same function except for the following points; hence only the operation of channel 0 is explained below.

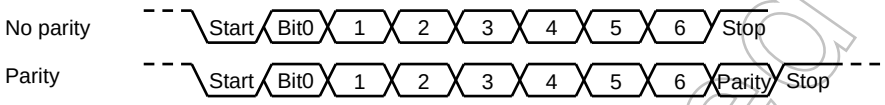
Table 3.9.1 Differences between Channels 0 to 1

	Channel 0	Channel 1	Channel 2
Pin name	TXD0 (PF0) RXD0 (PF1) $\overline{CTS0}$ /SCLK0 (PF2)	TXD1 (PF3) RXD1 (PF4) $\overline{CTS1}$/SCLK1 (PF5)	TXD2 (PD2) RXD2 (PD3) $\overline{CTS2}$ /SCLK2 (PD4)
IrDA mode	Yes	Yes	Yes

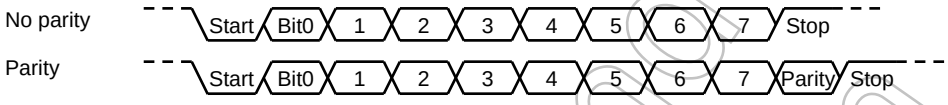
- Mode 0 (I/O interface mode)



- Mode 1 (7-bit UART mode)



- Mode 2 (8-bit UART mode)



- Mode 3 (9-bit UART mode)

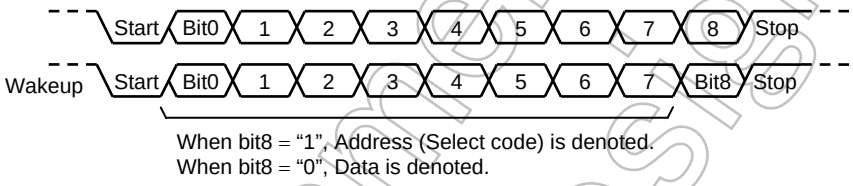


Figure 3.9.1 Data Formats

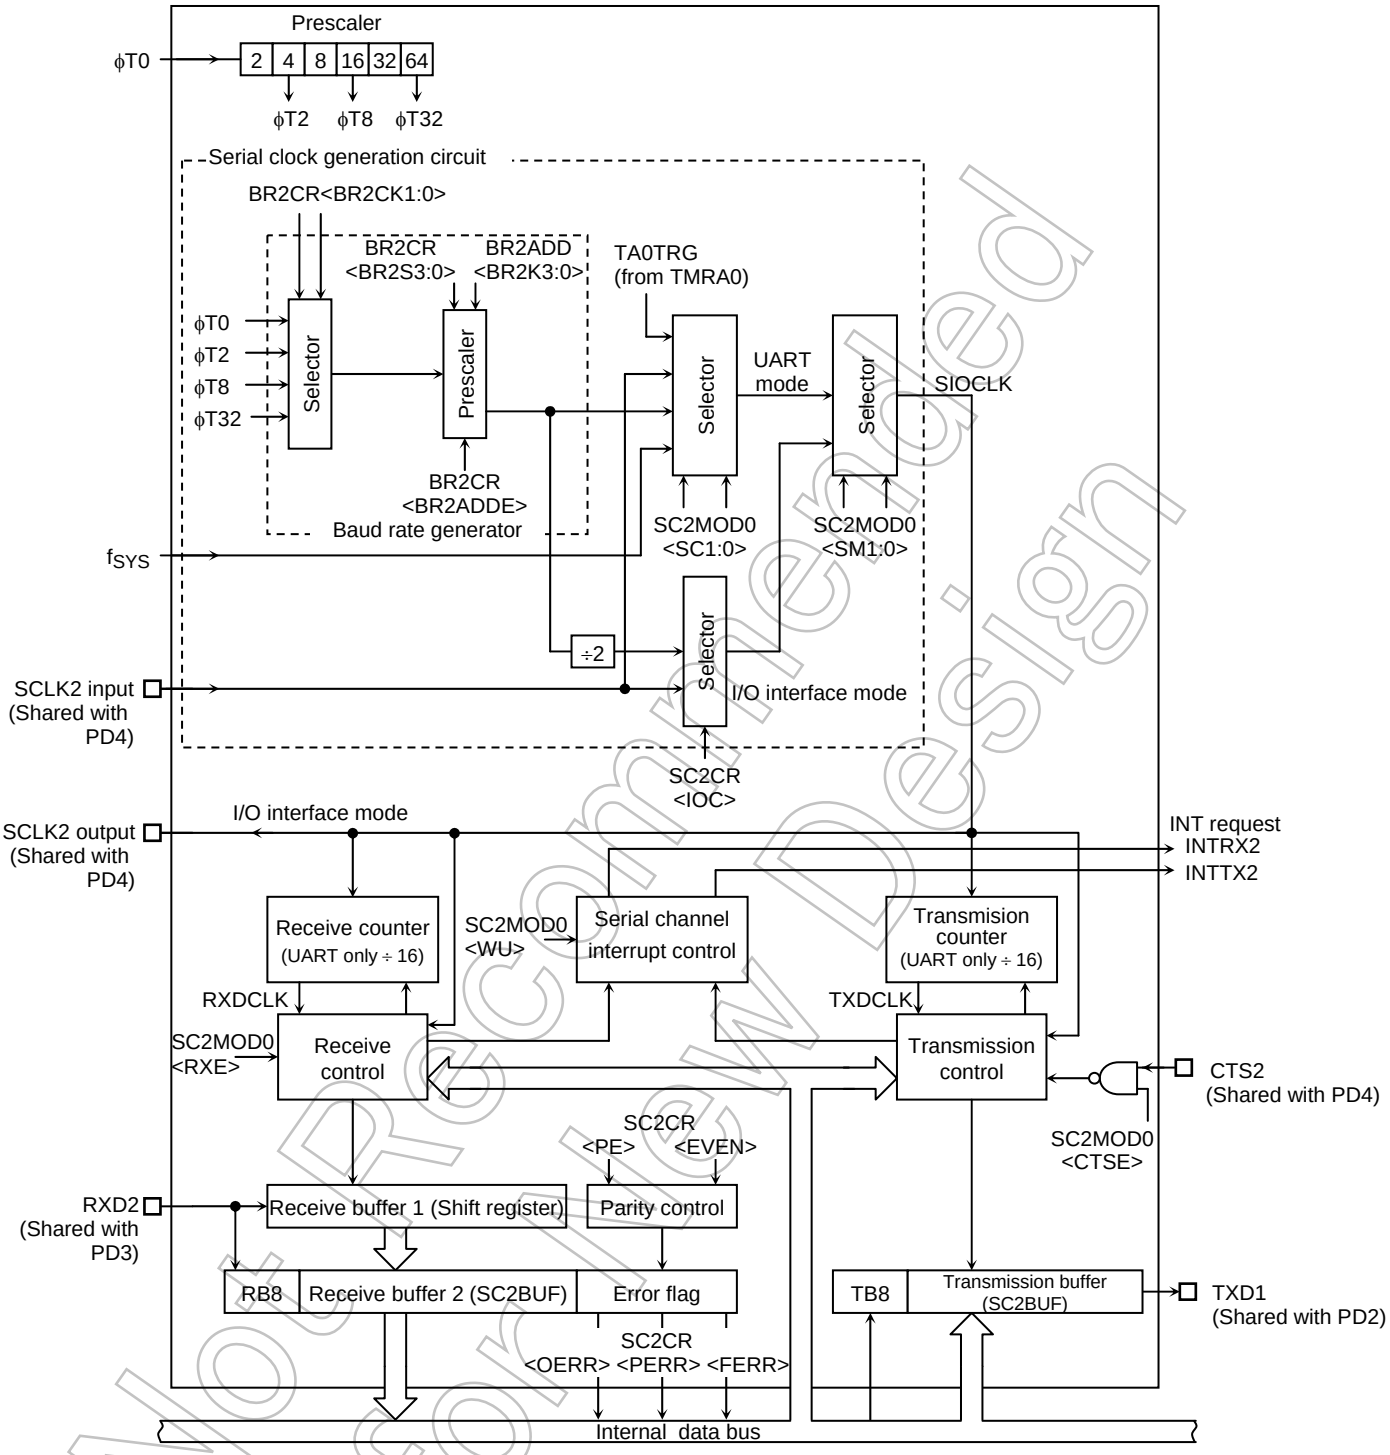

Figure 3.9.4 Block Diagram of Serial Channel 2

3.9.2 Operation for Each Circuit

(1) Prescaler

There is a 6-bit prescaler for generating a clock to SIO0.

The prescaler can be run only case of selecting the baud rate generator as the serial transfer clock.

Table 3.9.2 shows prescaler clock resolution into the baud rate generator.

Table 3.9.2 Prescaler Clock Resolution to Baud Rate Generator

System clock SYSCR1 <SYSCK>	Clock Gear SYSCR1 <GEAR2:0>	–	Clock Resolution BR0CR<BR0CK1:0>			
			ϕT0	ϕT2(1/4)	ϕT8(1/16)	ϕT32(1/64)
1(fs)	–	1/4	fs/4	fs/16	fs/64	fs/256
0 (fc)	000(1/1)		fc/4	fc/16	fc/64	fc/256
	001(1/2)		fc/8	fc/32	fc/128	fc/512
	010(1/4)		fc/16	fc/64	fc/256	fc/1024
	011(1/8)		fc/32	fc/128	fc/512	fc/2048
	100(1/16)		fc/64	fc/256	fc/1024	fc/4096

The baud rate generator selects between 4 clock inputs: ϕT0, ϕT2, ϕT8, and ϕT32 among the prescaler outputs.

(2) Baud rate generator

The baud rate generator is a circuit, which generates transmission and receiving clocks that determine the transfer rate of the serial channels.

The input clock to the baud rate generator, ϕT0, ϕT2, ϕT8 or ϕT32, is generated by the 6-bit SIO prescaler which is shared by the timers. One of these input clocks is selected using the BR0CR<BR0CK1:0> field in the baud rate generator control register.

The baud rate generator includes a frequency divider, which divides the frequency by 1 or N + (16 – K)/16 or 16 values, thereby determining the transfer rate.

The transfer rate is determined by the settings of BR0CR<BR0ADDE, BR0S3:0> and BR0ADD<BR0K3:0>.

- In UART mode

(1) When BR0CR<BR0ADDE> = "0"

The settings BR0ADD<BR0K3:0> are ignored. The baud rate generator divides the selected prescaler clock by N, which is set in BR0CK<BR0S3:0>. (N = 1, 2, 3 …16)

(2) When BR0CR<BR0ADDE> = "1"

The N + (16 – K)/16 division function is enabled. The baud rate generator divides the selected prescaler clock by N + (16 – K)/16 using the value of N set in BR0CR<BR0S3:0> (N = 2, 3…15) and the value of K set in BR0ADD<BR0K3:0> (K = 1, 2, 3…15)

Note: If N = 1 or N = 16, the N + (16 – K)/16 division function is disabled. Set BR0CR<BR0ADDE> to "0".

- In I/O interface mode

The N + (16 – K)/16 division function is not available in I/O interface mode. Clear BR0CR<BR0ADDE> to "0" before dividing by N.

The method for calculating the transfer rate when the baud rate generator is used is explained below.

- In UART mode

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

- In I/O interface mode

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 2$$

- Integer divider (N divider)

  For example, when the source clock frequency (f_C) is 12.288 MHz, the input clock is ϕT2 (f_C/16), the frequency divider N (BR0CR<BR0S3:0>) = 5, and BR0CR<BR0ADDE> = "0", the baud rate in UART mode is as follows:

  * Clock state ⌈High speed Clock gear : 1/1 (fc)

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

$$= \frac{f_C/16}{5} \div 16$$

$$= 12.288 \times 10^6 \div 16 \div 5 \div 16 = 9600 \text{ (bps)}$$

Note: The N + (16 – K)/16 division function is disabled and setting BR0ADD<BR0K3:0> is invalid.

- N + (16 – K)/16 divider (UART mode only)

  Accordingly, when the source clock frequency (f_C) = 4.8 MHz, the input clock is ϕT0 (f_C/4), the frequency divider N (BR0CR<BR0S3:0>) = 3, K (BR0ADD<BR0K3:0>) = 7, and BR0CR<BR0ADDE> = "1", the baud rate in UART mode is as follows:

  * Clock state ⌈High speed Clock gear : 1/1 (fc)

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

$$= \frac{f_C/4}{7 + \frac{(16 - 3)}{16}} \div 16$$

$$= 4.8 \times 10^6 \div 4 \div (7 + \frac{13}{16}) \div 16 = 9600 \text{ (bps)}$$

  Table 3.9.3 show examples of UART mode transfer rates.

  Additionally, the external clock input is available in the serial clock. (Serial channels 0, 1 and 2). The method for calculating the baud rate is explained below:

  - In UART mode

    Baud rate = external clock input frequency ÷ 16

    It is necessary to satisfy (External clock input cycle) ≥ 4/f_C

  - In I/O interface mode

    Baud rate = external clock input frequency

    It is necessary to satisfy (External clock input cycle) ≥ 16/f_C

Table 3.9.3 Selection of Transfer Rate

(when baud rate generator is used and BR0CR<BR0ADDE> = "0")

Unit (Kbps)

f_C [MHz]	Input Clock / Frequency Divider	φT0 (f_C/4)	φT2 (f_C/16)	φT8 (f_C/64)	φT32 (f_C/256)
9.8304	2	76.800	19.200	4.800	1.200

22.1184	3	115.200	28.800	7.200	1.800
24.5760	1	384.000	96.000	24.000	6.000
↑	2	192.000	48.000	12.000	3.000
↑	4	96.000	24.000	6.000	1.500
↑	5	76.800	19.200	4.800	1.200
↑	8	48.000	12.000	3.000	0.750
↑	A	38.400	9.600	2.400	0.600
↑	10	24.000	6.000	1.500	0.375

Note1: Transfer rates in I/O interface mode are eight times faster than the values given above.

In UART mode, TMRA match detect signal (TA0TRG) can be used for serial transfer clock.

Method for calculating the timer output frequency which is needed when outputting trigger of timer

TA0TRG frequency = Baud rate × 16

Note2: The TMRA0 match detect signal cannot be used as the transfer clock in I/O Interface mode.

(3) Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

- In I/O interface mode

  In SCLK output mode with the setting SC0CR<IOC> = "0", the basic clock is generated by dividing the output of the baud rate generator by 2, as described previously.

  In SCLK input mode with the setting SC0CR<IOC> = "1", the rising edge or falling edge will be detected according to the setting of the SC0CR<SCLKS> register to generate the basic clock.

- In UART mode

  The SC0MOD0<SC1:0> setting determines whether the baud rate generator clock, the internal clock f_{SYS}, the match detect signal from TMRA0 or the external clock (SCLK0) is used to generate the basic clock SIOCLK.

(4) Receiving counter

The receiving counter is a 4-bit binary counter used in UART mode, which counts up the pulses of the SIOCLK clock. It takes 16 SIOCLK pulses to receive 1 bit of data; each data bit is sampled three times on the 7th, 8th and 9th clock cycles.

The value of the data bit is determined from these three samples using the majority rule.

For example, if the data bit is sampled respectively as "1", "0" and "1" on 7th, 8th and 9th clock cycles, the received data bit is taken to be "1". A data bit sampled as "0", "0" and "1" is taken to be "0".

(5) Receiving control

- In I/O interface mode

  In SCLK output mode with the setting SC0CR<IOC> = "0", the RXD0 signal is sampled on the rising edge or falling of the shift clock which is output on the SCLK0 pin, according to the SC0CR<SCLKS> setting.

  In SCLK input mode with the setting SC0CR<IOC> = "1", the RXD0 signal is sampled on the rising or falling edge of the SCLK0 input, according to the SC0CR<SCLKS> setting.

- In UART mode

  The receiving control block has a circuit, which detects a start bit using the majority rule. Received bits are sampled three times; when two or more out of three samples are "0", the bit is recognized as the start bit and the receiving operation commences.

  The values of the data bits that are received are also determined using the majority rule.

(6) The receiving buffers

To prevent overrun errors, the receiving buffers are arranged in a double buffer structure.

Received data is stored one bit at a time in receiving buffer 1 (which is a shift register). When 7 or 8 bits of data have been stored in receiving buffer 1, the stored data is transferred to receiving buffer 2 (SC0BUF); this causes an INTRX0 interrupt to be generated. The CPU only reads receiving buffer 2 (SC0BUF). Even before the CPU reads receiving buffer 2 (SC0BUF), the received data can be stored in receiving buffer 1. However, unless receiving buffer 2 (SC0BUF) is read before all bits of the next data are received by receiving buffer 1, an overrun error occurs. If an overrun error occurs, the contents of receiving buffer 1 will be lost, although the contents of receiving buffer 2 and SC0CR<RB8> will be preserved.

SC0CR<RB8> is used to store either the parity bit – added in 8-bit UART mode – or the most significant bit (MSB) – in 9-bit UART mode.

In 9-bit UART mode the wakeup function for the slave controller is enabled by setting SC0MOD0<WU> to "1"; in this mode INTRX0 interrupts occur only when the value of SC0CR<RB8> is "1".

SIO interrupt mode is selectable by the register SIMC.

(7) Transmission counter

The transmission counter is a 4-bit binary counter used in UART mode and which, like the receiving counter, counts the SIOCLK clock pulses; a TXDCLK pulse is generated every 16 SIOCLK clock pulses.

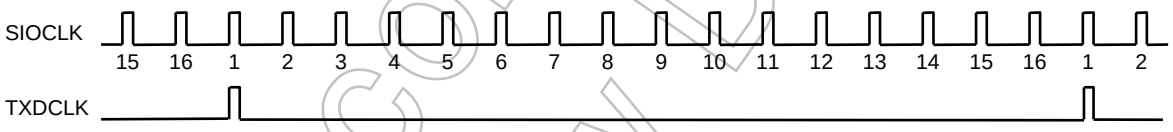

Figure 3.9.5 Generation of the Transmission Clock

(8) Transmission controller

- In I/O interface mode

In SCLK output mode with the setting SC0CR<IOC> = "0", the data in the transmission buffer is output one bit at a time to the TXD0 pin on the rising or falling edge of the shift clock which is output on the SCLK0 pin, according to the SC0CR<SCLKS> setting.

In SCLK input mode with the setting SC0CR<IOC> = "1", the data in the transmission buffer is output one bit at a time on the TXD0 pin on the rising or falling edge of the SCLK0 input, according to the SC0CR<SCLKS> setting.

- In UART mode

When transmission data sent from the CPU is written to the transmission buffer, transmission starts on the rising edge of the next TXDCLK.

Handshake function

Use of $\overline{CTS}$ pin allows data to be sent in units of one frame; thus, overrun errors can be avoided. The handshake function is enabled or disabled by the SC0MOD<CTSE> setting.

When the $\overline{CTS0}$ pin goes high on completion of the current data send, data transmission is halted until the $\overline{CTS0}$ pin goes low again. However, the INTTX0 interrupt is generated, and it requests the next data send from the CPU. The next data is written in the transmission buffer and data sending is halted.

Though there is no $\overline{RTS}$ pin, a handshake function can be easily configured by setting any port assigned to be the $\overline{RTS}$ function. The $\overline{RTS}$ should be output "high" to request send data halt after data receive is completed by software in the RXD interrupt routine.

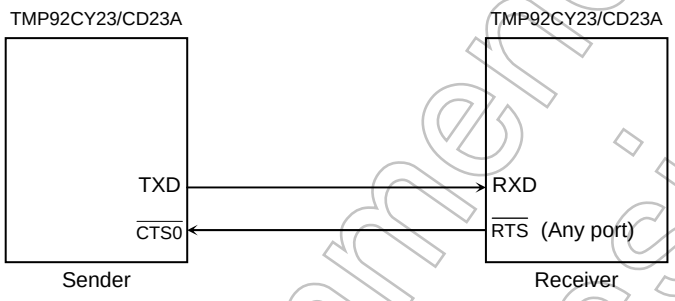

Figure 3.9.6 Handshake Function

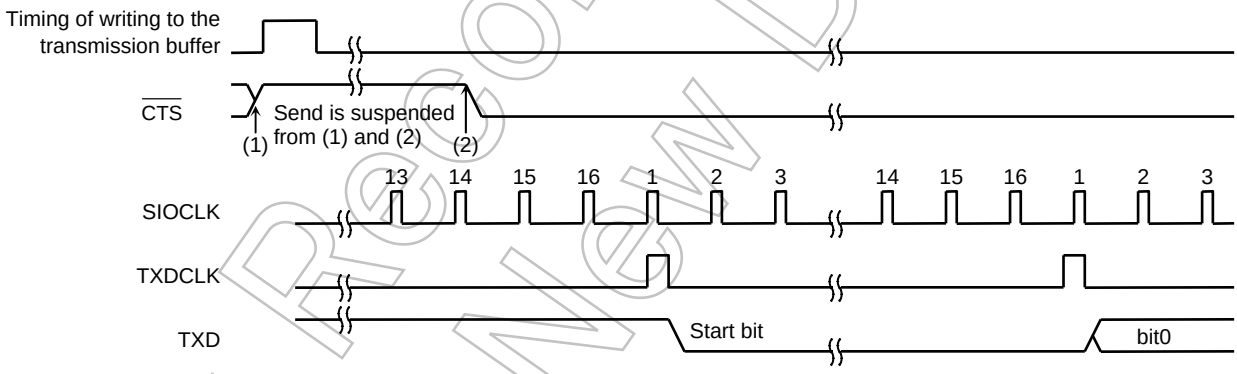

Note 1: If the $\overline{CTS}$ signal goes high during transmission, no more data will be sent after completion of the current transmission.

Note 2: Transmission starts on the first falling edge of the TXDCLK clock after the $\overline{CTS}$ signal has fallen.

Figure 3.9.7 $\overline{CTS}$ (Clear to send) Timing

(9) Transmission buffer

The transmission buffer (SC0BUF) shifts out and sends the transmission data written from the CPU in order from the least significant bit (LSB). When all the bits are shifted out, the transmission buffer becomes empty and generates an INTTX0 interrupt.

(10) Parity control circuit

When SC0CR<PE> in the serial channel control register is set to "1", it is possible to transmit and receive data with parity. However, parity can be added only in 7-bit UART mode or 8-bit UART mode. The SC0CR<EVEN> field in the serial channel control register allows either even or odd parity to be selected.

In the case of transmission, parity is automatically generated when data is written to the transmission buffer SC0BUF. The data is transmitted after the parity bit has been stored in SC0BUF<TB7> in 7-bit UART mode or in SC0MOD0<TB8> in 8-bit UART mode. SC0CR<PE> and SC0CR<EVEN> must be set before the transmission data is written to the transmission buffer.

In the case of receiving, data is shifted into receiving buffer 1, and the parity is added after the data has been transferred to receiving buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> in 7-bit UART mode or with SC0CR<RB8> in 8-bit UART mode. If they are not equal, a parity error is generated and the SC0CR<PERR> flag is set.

(11) Error flags

Three error flags are provided to increase the reliability of data reception.

1. Overrun error <OERR>

If all the bits of the next data item have been received in receiving buffer 1 while valid data still remains stored in receiving buffer 2 (SC0BUF), an overrun error is generated.

The below is a recommended flow when the overrun-error is generated.

(INTRX interrupt routine)

1) Read receiving buffer
2) Read error flag
3) If <OERR> = "1"

then

a) Set to disable receiving (Write "0" to SC0MOD0<RXE>)
b) Wait to terminate current frame
c) Read receiving buffer
d) Read error flag
e) Set to enable receiving (Write "1" to SC0MOD0<RXE>)
f) Request to transmit again

4) Other

2. Parity error <PERR>

The parity generated for the data shifted into receiving buffer 2 (SC0BUF) is compared with the parity bit received via the RXD pin. If they are not equal, a parity error is generated.

3. Framing error <FERR>

The stop bit for the received data is sampled three times around the center. If the majority of the samples are "0", a framing error is generated.

(12) Timing generation

1. In UART mode

Receiving

Mode	9 Bits (Note)	8 Bits + Parity (Note)	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt Timing	Center of last bit (bit8)	Center of last bit (parity bit)	Center of stop bit
Framing Error Timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity Error Timing	–	Center of last bit (parity bit)	Center of stop bit
Overrun Error Timing	Center of last bit (bit8)	Center of last bit (parity bit)	Center of stop bit

Note1: In 9-bit and 8-bit parity modes, interrupts coincide with the ninth bit pulse. Thus, when servicing the interrupt, it is necessary to wait for a 1-bit period (to allow the stop bit to be transferred) to allow checking for a framing error.

Transmitting

Mode	9 Bits	8 Bits + Parity	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt Timing	Just before stop bit is transmitted	Just before stop bit is transmitted	Just before stop bit is transmitted

2. I/O interface

Transmission Interrupt Timing	SCLK output mode	Immediately after last bit data. (See Figure 3.9.25.)
	SCLK input mode	Immediately after rise of last SCLK signal rising mode, or immediately after fall in falling mode. (See Figure 3.9.26.)
Receiving Interrupt Timing	SCLK output mode	Timing used to transfer received to data receive buffer 2 (SC0BUF) (e.g. immediately after last SCLK). (See Figure 3.9.27.)
	SCLK input mode	Timing used to transfer received data to receive buffer 2 (SC0BUF) (e.g. immediately after last SCLK). (See Figure 3.9.28.)

3.9.4 Operation in Each Mode

(1) Mode 0 (I/O interface mode)

This mode allows an increase in the number of I/O pins available for transmitting data to or receiving data from an external shift register.

This mode includes the SCLK output mode to output synchronous clock SCLK and SCLK input mode to input external synchronous clock SCLK.

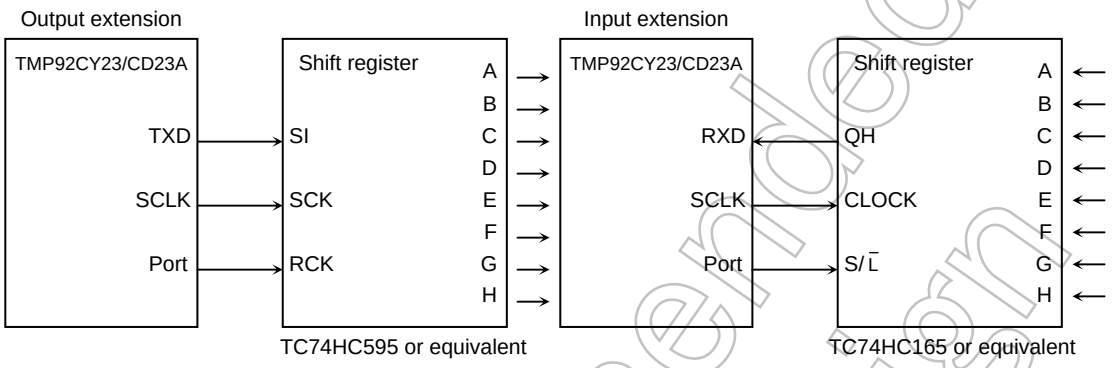

Figure 3.9.23 SCLK Output Mode Connection Example

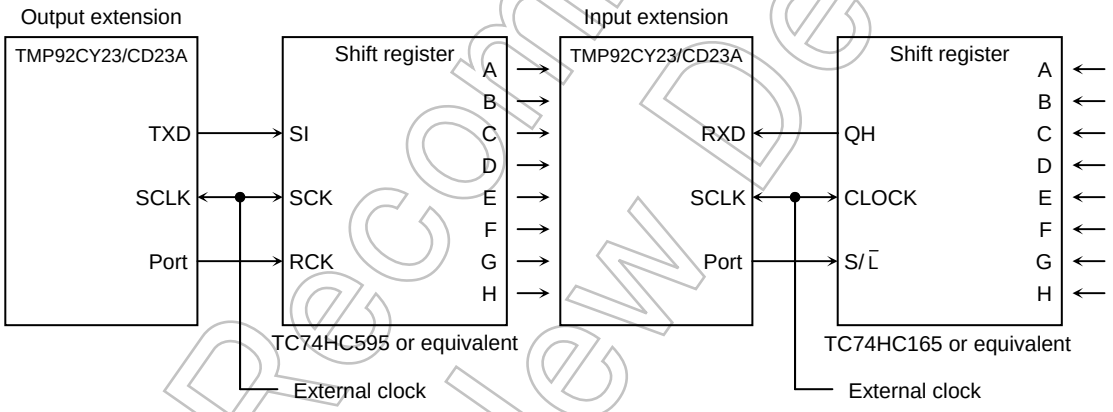

Figure 3.9.24 Example of SCLK Input Mode Connection

1. Transmission

In SCLK output mode 8-bit data and a synchronous clock are output on the TXD0 and SCLK0 pins respectively each time the CPU writes data to the transmission buffer. When all data is output, INTES0<ITX0C> will be set to generate the INTTX0 interrupt.

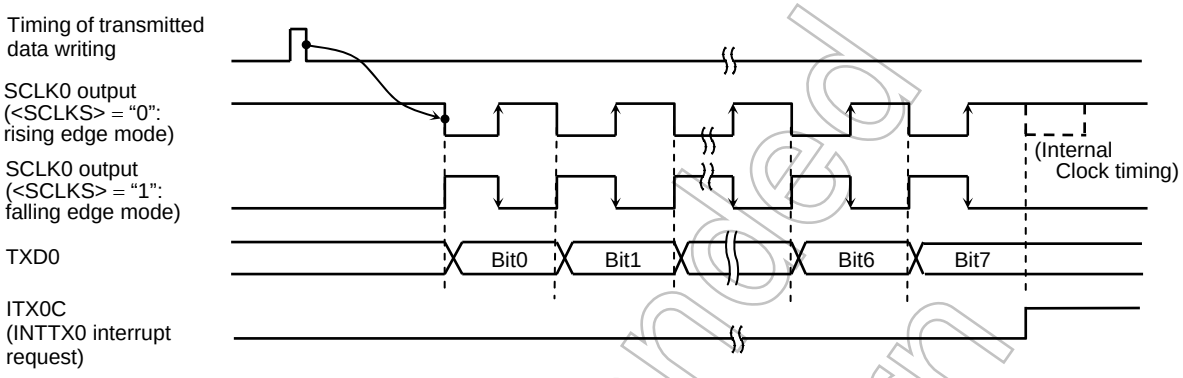

Figure 3.9.25 Transmitting Operation in I/O Interface Mode (SCLK0 output mode)

In SCLK input mode, 8-bit data is output on the TXD0 pin when the SCLK0 input becomes active after the data has been written to the transmission buffer by the CPU.

When all data is output, INTES0<ITX0C> will be set to generate an INTTX0 interrupt.

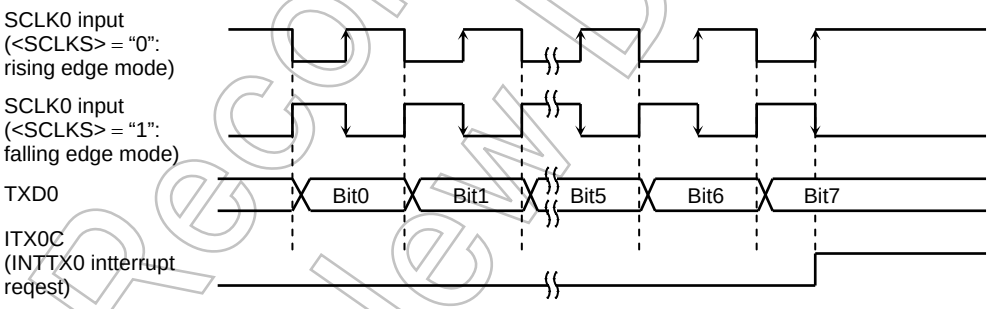

Figure 3.9.26 Transmitting Operation in I/O Interface Mode (SCLK0 input mode)

2. Receiving

In SCLK output mode the synchronous clock is output on the SCLK0 pin and the data is shifted to receiving buffer 1. This is initiated when the receive interrupt flag INTES0<IRX0C> is cleared as the received data is read. When 8-bit data is received, the data is transferred to receiving buffer 2 (SC0BUF) following the timing shown below and INTES0<IRX0C> is set to "1" again, causing an INTRX0 interrupt to be generated.

Setting SC0MOD0<RXE> to "1" initiates SCLK0 output.

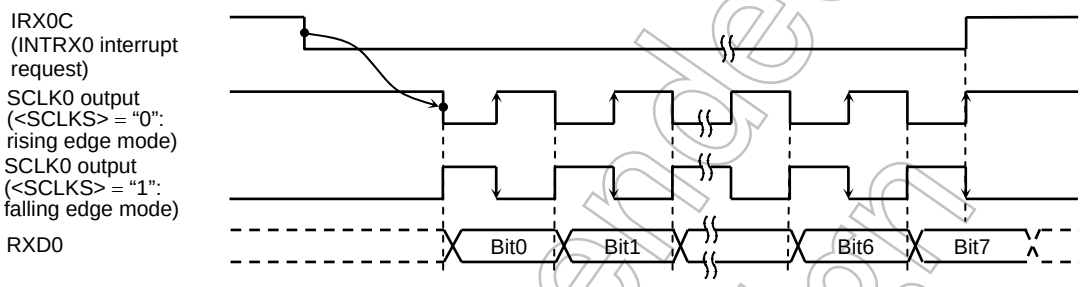

Figure 3.9.27 Receiving Operation in I/O Interface Mode (SCLK0 output mode)

In SCLK input mode the data is shifted to receiving buffer 1 when the SCLK input goes active. The SCLK input goes active when the receive interrupt flag INTES0<IRX0C> is cleared as the received data is read. When 8-bit data is received, the data is shifted to receiving buffer 2 (SC0BUF) following the timing shown below and INTES0<IRX0C> is set to "1" again, causing an INTRX0 interrupt to be generated.

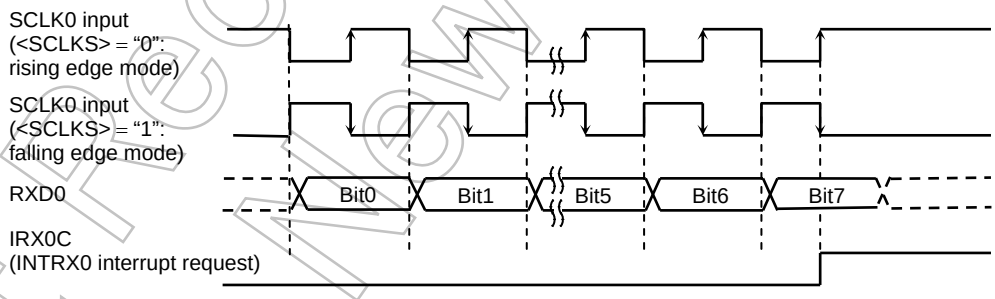

Figure 3.9.28 Receiving Operation in I/O Interface Mode (SCLK0 input mode)

Note: The system must be put in the receive-enable state (SC0MOD0<RXE> = "1") before data can be received.

3. Transmission and receiving (Full duplex mode)

When full duplex mode is used, set the receive interrupt level to 0, and only set the interrupt level (from 1 to 6) of the the transmig interrupt. Ensure that the program which transmits the interrupt reads the receiving buffer before setting the next transmit data.

The following is an example of this:

Example: Channel 0, SCLK output
Baud rate = 9600 bps
fc = 14.7456 MHz
*Clock condition: Clock gear 1/1(fc)

Main routine

	7	6	5	4	3	2	1	0	
INTES0	X	0	0	1	X	0	0	0	Set the INTTX0 level to 1. Set the INTRX0 level to 0.
PFCR	–	–	–	–	–	1	0	1	Set PF0, PF1 and PF2 to function as the TXD0, RXD0 and SCLK0 pins respectively.
PFFC	–	–	–	–	–	1	1	1	
SC0MOD0	0	0	0	0	0	0	0	0	Select I/O interface mode.
SC0MOD1	1	1	0	0	0	0	0	0	Select full duplex mode.
SC0CR	0	0	0	0	0	0	0	0	Set the SCLK output, transmit on negative edge, and receive on positive edge.
BR0CR	0	0	1	1	0	0	1	1	Set to 9600 bps.
SC0MOD0	0	0	1	0	0	0	0	0	Set receive to enable.
SC0BUF	*	*	*	*	*	*	*	*	Set the transmit data and start.

INTTX0 interrupt routine

A_{CC}	←	SC0BUF							Read the receiving buffer.
SC0BUF		*	*	*	*	*	*	*	Set the next transmit data.

X: Don't care, –: No change

(2) Mode 1 (7-bit UART mode)

7-bit UART mode is selected by setting the serial channel mode register SC0MOD0<SM1:0> field to "01".

In this mode a parity bit can be added. Use of a parity bit is enabled or disabled by the setting of the serial channel control register SC0CR<PE> bit; whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to "1" (enabled).

Setting example: When transmitting data of the following format, the control registers should be set as described below.

Transmission direction (Transmission rate: 2400 bps at f_{SYS} = 19.6608 MHz)

*Clock condition: Clock gear 1/1(fc)

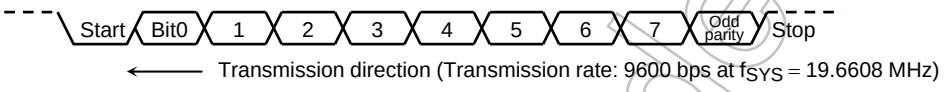
		7	6	5	4	3	2	1	0	
PFCR	←	–	–	–	–	–	–	–	1	Set PF0 to function as the TXD0 pin.
PFFC	←	–	–	–	–	–	–	–	1	
SC0MOD0	←	X	0	–	X	0	1	0	1	Select 7-bit UART mode.
SC0CR	←	X	1	1	X	X	X	0	0	Add even parity.
BR0CR	←	0	0	1	0	1	0	0	0	Set to 2400 bps.
INTES0	←	X	1	0	0	–	–	–	–	Set INTTX0 interrupt to enable and set to level 4.
SC0BUF	←	*	*	*	*	*	*	*	*	Set the transmit data.

X: Don't care, –: No change

(3) Mode 2 (8-bit UART mode)

8-bit UART mode is selected by setting SC0MOD0<SM1:0> to "10". In this mode a parity bit can be added (use of a parity bit is enabled or disabled by the setting of SC0CR<PE>); whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to "1" (enabled).

Setting example: When receiving data of the following format, the control registers should be set as described below.



← Transmission direction (Transmission rate: 9600 bps at f_{SYS} = 19.6608 MHz)

Main settings

		7	6	5	4	3	2	1	0	
PFCR	←	–	–	–	–	–	–	0	–	Set PF1 to function as the RXD0 pin.
PFFC	←	–	–	–	–	–	–	1	–	
SC0MOD0	←	–	0	1	X	1	0	0	1	Enable receiving in 8-bit UART mode.
SC0CR	←	X	0	1	X	X	X	0	0	Add odd parity.
BR0CR	←	0	0	0	1	1	0	0	0	Set to 9600 bps.
INTES0	←	–	–	–	–	X	1	0	0	Set INTTX0 interrupt to enable and set to level 4.

Interrupt processing

A_{CC} ← SC0CR AND 00011100
if A_{CC} ≠ 0 then ERROR } Check for errors

A_{CC} ← SC0BUF Read the received data

X: Don't care, –: No change

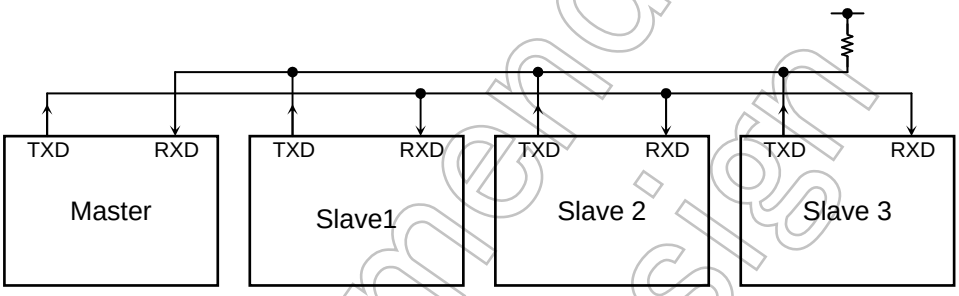
(4) Mode 3 (9-bit UART mode)

9-bit UART mode is selected by setting SC0MOD0<SM1:0> to "11". In this mode parity bit cannot be added.

In the case of transmission the MSB (9th bit) is written to SC0MOD0<TB8>. In the case of receiving it is stored in SC0CR<RB8>. When the buffer is written or read, the <TB8> or <RB8> is read or written first, before the rest of the SC0BUF data.

Wakeup function

In 9-bit UART mode, the wakeup function for slave controllers is enabled by setting SC0MOD0<WU> to "1". The interrupt INTRX0 can only be generated when<RB8> = "1".

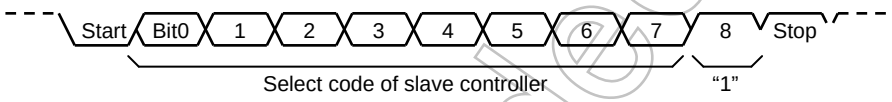


Note: The TXD pin of each slave controller must be in open-drain output mode.

Figure 3.9.29 Serial Link Using Wakeup Function

Protocol

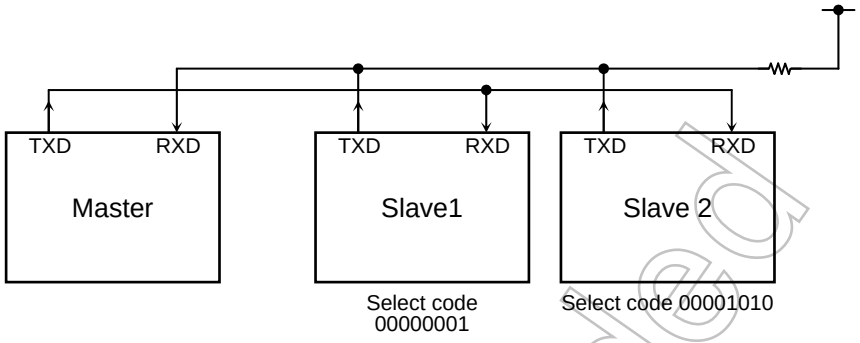
1. Select 9-bit UART mode on the master and slave controllers.
2. Set the SC0MOD0<WU> bit on each slave controller to "1" to enable data receiving.
3. The master controller transmits data one frame at a time. Each frame includes an 8-bit select code which identifies a slave controller. The MSB (bit8) of the data (<TB8>) is set to "1".



4. Each slave controller receives the above frame. Each controller checks the above select code against its own select code. The controller whose code matches clears its <WU> bit to "0".
5. The master controller transmits data to the specified slave controller (the controller whose SC0MOD0<WU> bit has been cleared to 0). The MSB (bit8) of the data (<TB8>) is cleared to "0".

6. The other slave controllers (whose <WU> bits remain at "1") ignore the received data because their MSBs (bit8 or <RB8>) are set to "0", disabling INTRX0 interrupts.
   The slave controller whose <WU> bit = "0" can also transmit to the master controller. In this way it can signal the master controller that the data transmission from the master controller has been completed.

Setting example: To link two slave controllers serially with the master controller using the internal clock f_{SYS} as the transfer clock.



- Setting the master controller

Main

PFCR	← – – – – – – 0 1	Set PF0 and PF1 to function as the TXD0 and RXD0 pins respectively.
PFFC	← – – – – – – 1 1	
INTES0	← X 1 0 0 X 1 0 1	Set INTTX0 to enable, and set interrupt level to level 4. Set INTRX0 to enable, and set interrupt level to level 5.
SC0MOD0	← 1 0 1 0 1 1 1 0	Set f_{SYS} as the transmission clock for 9-bit UART mode.
SC0BUF	← 0 0 0 0 0 0 0 1	Set the select code for slave controller 1.
INTTX0 interrupt		
SC0MOD0	← 0 – – – – – – –	Set TB8 to "0".
SC0BUF	← * * * * * * * *	Set the transmission data.

- Setting the slave controller

Main

PFCR	← – – – – – – 0 1	Set PF1 and PF0 to function as the RXD0 and TXD0 pins respectively.
PFFC	← – – – – – – 1 1	
INTES0	← X 1 0 0 X 1 0 1	Set INTRX0 to enable, and set interrupt level to level 4. Set INTRX0 to enable, and set interrupt level to level 5
SC0MOD0	← 0 0 1 1 1 1 1 0	Set to <WU> = "1" in 9-bit UART mode transfer clock f_{SYS}.
INTRX0 interrupt		
A_{CC}	← SC0BUF	
if A_{CC} = select code		
Then SC0MOD0	← – – – 0 – – – –	Clear <WU> to "0"

3.9.5 Support for IrDA

SIO0, SIO1 and SIO2 include support for the IrDA 1.0 infrared data communication specification.

Figure 3.9.30 shows the block diagram.

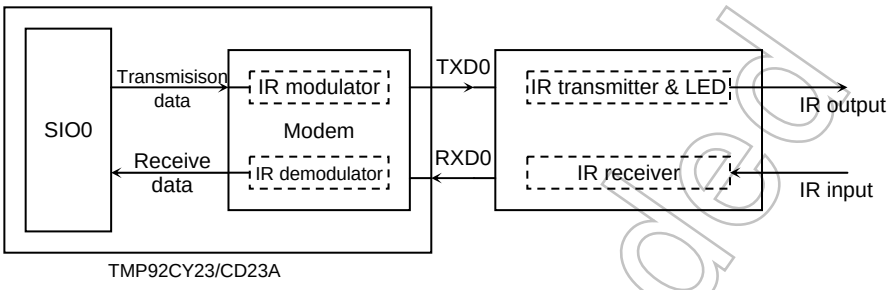


Figure 3.9.30 Block Diagram

(1) Modulation of the transmission data

When the transmit data is "0", the modem outputs 1 to TXD0 pin with either 3/16 or 1/16 times for width of baud rate. The pulse width is selected by the SIR0CR<PLSEL>.

When the transmit data is "1", the modem outputs "0".

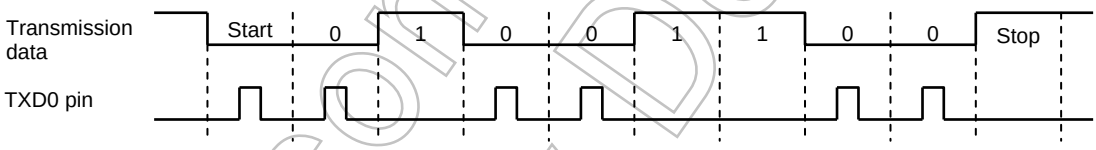

Figure 3.9.31 Transmission Example (SIO0)

(2) Modulation of the receive data

When the receive data has an effective pulse of "1", the modem outputs "0" to SIO0. Otherwise the modem outputs "1" to SIO0. The effective pulse width is selected by SIR0CR<SIR0WD3:0>.

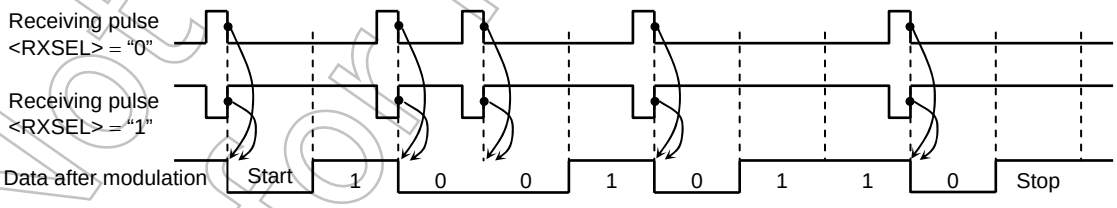

Figure 3.9.32 Receiving Example (SIO0)

(3) Data format

The data format is fixed as follows:

- Data length: 8 bits
- Parity bits: none
- Stop bits: 1 bit

(4) SFR

Figure 3.9.33, Figure 3.9.34 and Figure 3.9.35 show the control register SIR0CR, SIR1CR and SIR2CR. Set SIRxCR data while SIOx is stopped. The following example describes how to set this register:

```
1) SIO setting                          ;  Set the SIO to UART mode.
   ↓
2) LD      (SIR0CR), 07H                ;  Set the receive data pulse width to 16×+100ns.
3) LD      (SIR0CR), 37H                ;  TXEN, RXEN Enable the transmission and receiving.
   ↓
4) Start transmission                   ;  The modem operates as follows:
   and receiving for SIO0                    • SIO0 starts transmitting.
                                             • IR receiver starts receiving.
```

(5) Notes

1. Baud rate for IrDA

   When IrDA is operated, set "01" to SC0MOD0<SC1:0> to generate baud rate.

   Setting other than the above (TA0TRG, f_{IO} and SCLK0 input) cannot be used.

2. The pulse width for transmission

   The IrDA 1.0 specification is defined in Table 3.9.4.

Table 3.9.4 Baud Rate and Pulse Width Specifications

Baud Rate	Modulation	Rate Tolerance (% of rate)	Pulse Width (min)	Pulse Width (typ.)	Pulse Width (max)
2.4 kbps	RZI	±0.87	1.41 μs	78.13 μs	88.55 μs
9.6 kbps	RZI	±0.87	1.41 μs	19.53 μs	22.13 μs
19.2 kbps	RZI	±0.87	1.41 μs	9.77 μs	11.07 μs
38.4 kbps	RZI	±0.87	1.41 μs	4.88 μs	5.96 μs
57.6 kbps	RZI	±0.87	1.41 μs	3.26 μs	4.34 μs
115.2 kbps	RZI	±0.87	1.41 μs	1.63 μs	2.23 μs

The pulse width is defined as either baud rate T × 3/16 or 1.6 μs (1.6 μs is equal to 3/16 pulse width when baud rate is 115.2 Kbps).

The TMP92CY23/CD23A has a function which can select the pulse width of transmission as either 3/16 or 1/16. However, 1/16 pulse width can only be selected when the baud rate is equal to or less than 38.4 Kbps.

For the same reason, the + (16 – K)/16 division function in the baud rate generator of SIO0 cannot be used to generate a 115.2 Kbps baud rate.

The + (16 – K)/16 division function cannot be used also when the baud rate is 38.4 Kbps and the pulse width 1/16.

Table 3.9.5 Baud Rate and Pulse Width for (16 – K)/16 Division Function

Pulse Width	Baud Rate					
	115.2 Kbps	57.6 Kbps	38.4 Kbps	19.2 Kbps	9.6 Kbps	2.4 Kbps
T × 3/16	×	○	○	○	○	○
T × 1/16	–	–	×	○	○	○

○: (16 – K)/16 division function can be used.

×: (16 – K)/16 division function cannot be used.

–: 1/16 pulse width cannot be used.

Figure 3.9.35 IrDA Control Register 2 (for SIO2)

3.10 Serial Bus Interface (SBI)

The TMP92CY23/CD23A has 2-channel serial bus interface which employs a clocked-synchronous 8-bit SIO mode and an I²C bus mode. They are called SBI0 and SBI1.

The serial bus interface is connected to an external device through PN1 (SDA0) and PN2 (SCL0), PN4 (SDA1) and PN5 (SCL1) in the I²C bus mode; and through PN0 (SCK0), PN1 (SO0), PN2 (SI0), PN3 (SCK1), PN4 (SO1) and PN5 (SI1) in the clocked-synchronous 8-bit SIO mode.

Each of the channels can be operated independently. Since both SBI0 and SBI1 channels operate in the same manner, a channel explains only the case of SBI0.

Each pin is specified as follows: (SBI0)

	PNCR<PN2C, PN1C, PN0C>	PNFC<PN2F, PN1F, PN0F>
I^2C Bus Mode	11X	11X
Clocked Synchronous 8-Bit SIO Mode	011 010	X11

Each pin is specified as follows: (SBI1)

	PNCR<PN5C, PN4C, PN3C>	PNFC<PN5F, PN4F, PN3F>
I^2C Bus Mode	11X	11X
Clocked Synchronous 8-Bit SIO Mode	011 010	X11

X: Don't care

3.10.1 Configuration

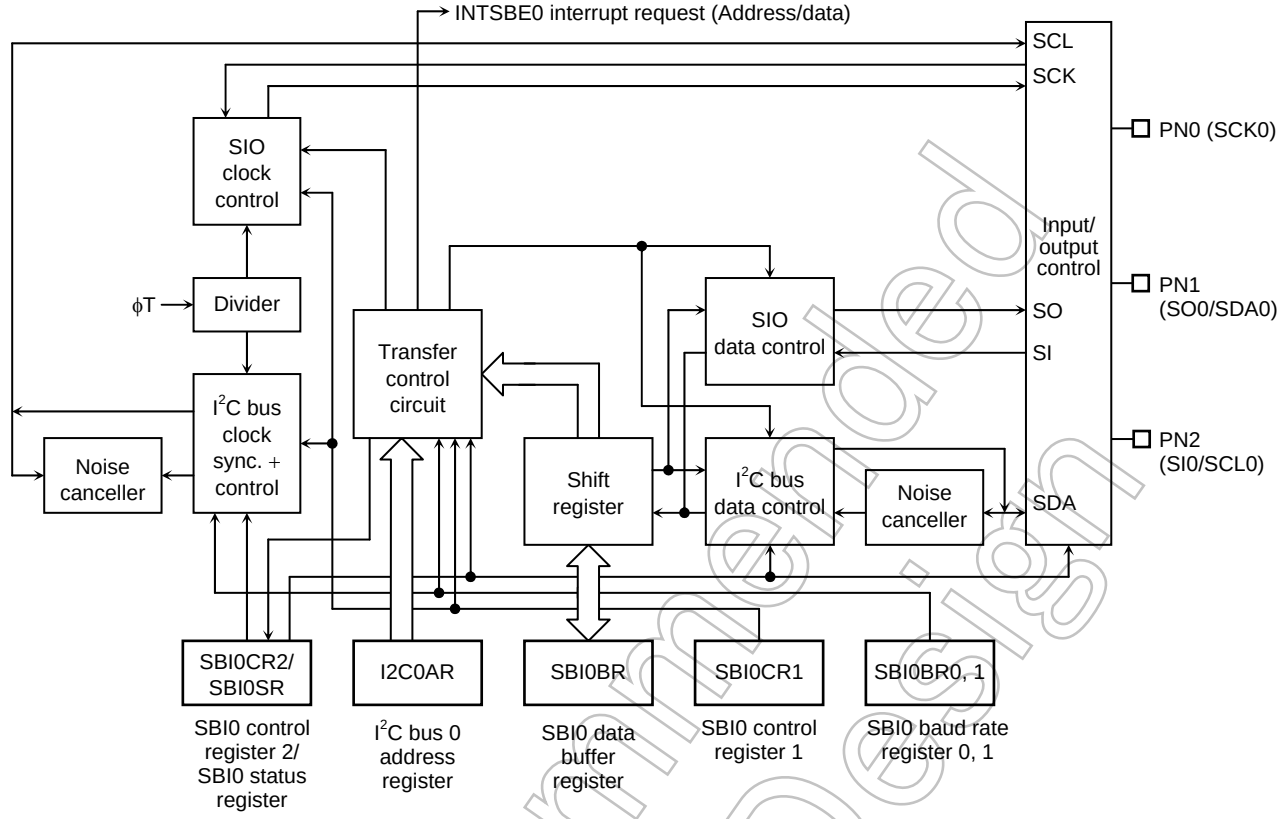

Figure 3.10.1 Serial Bus Interface 0 (SBI0)

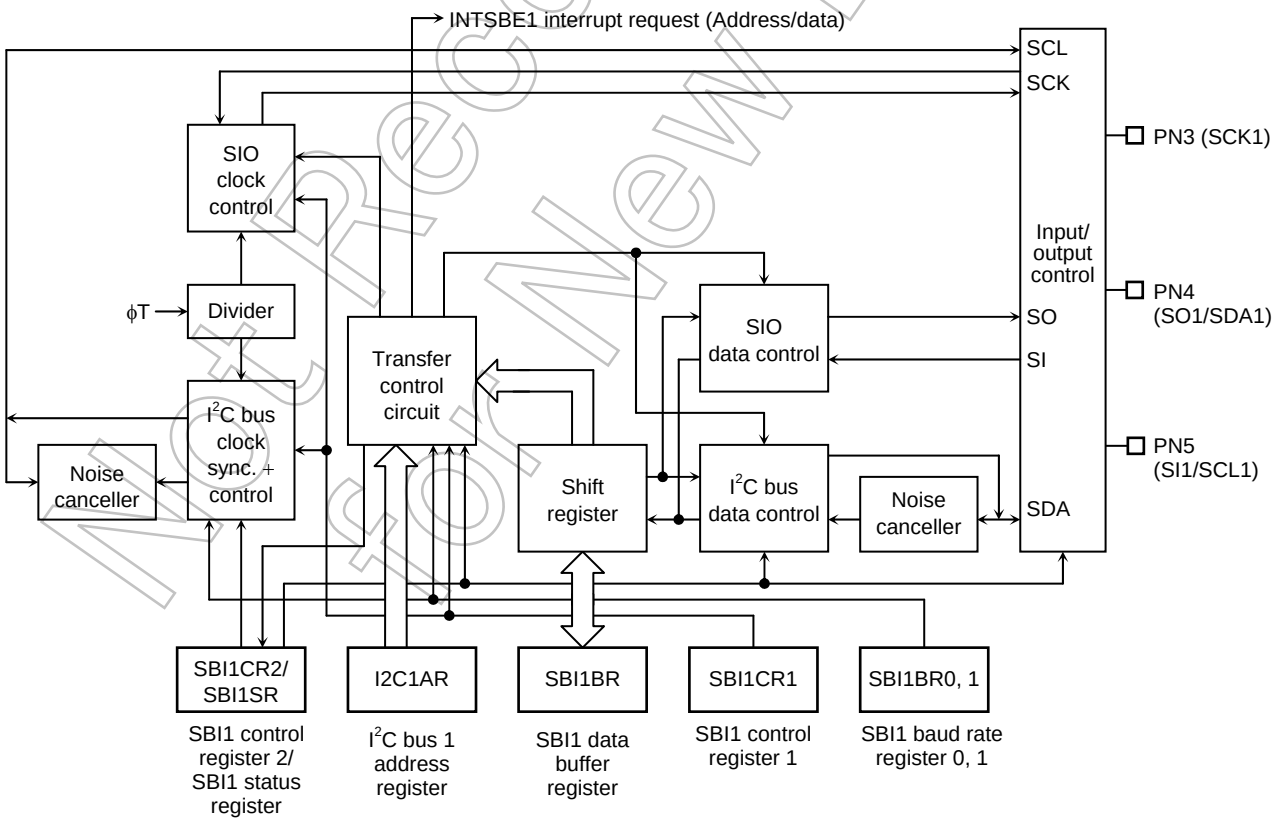

Figure 3.10.2 Serial Bus Interface 1 (SBI1)

3.10.2 Serial Bus Interface (SBI) Control

The following registers are used to control the serial bus interface and monitor the operation status.

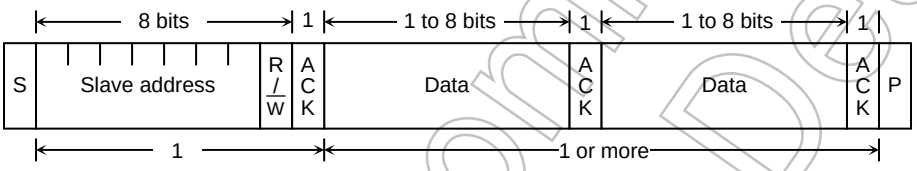
- Serial bus interface 0 control register 1 (SBI0CR1), (SBI1CR1)
- Serial bus interface 0 control register 2 (SBI0CR2), (SBI1CR2)
- Serial bus interface 0 data buffer register (SBI0DBR), (SBI1DBR)
- I2C bus 0 address register (I2C0AR), (I2C1AR)
- Serial bus interface 0 status register (SBI0SR), (SBI1SR)
- Serial bus interface 0 baud rate register 0 (SBI0BR0), (SBI1BR0)
- Serial bus interface 0 baud rate register 1 (SBI0BR1), (SBI1BR1)

The above registers differ depending on a mode to be used. Refer to section 3.10.4 "I2C Bus Mode Control Register" and 3.10.7 "Clocked-synchronous 8-Bit SIO Mode Control".

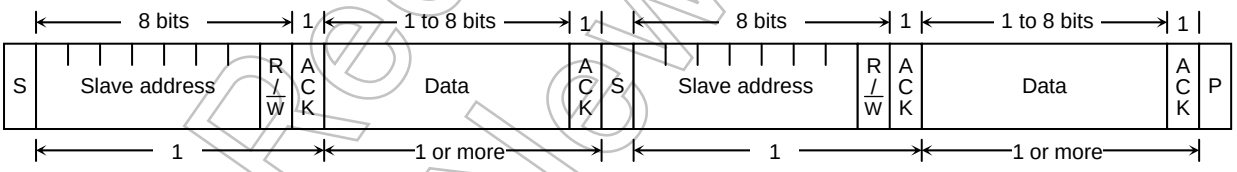
3.10.3 The Data Formats in the I2C Bus Mode

The data formats in the I2C bus mode are shown below.

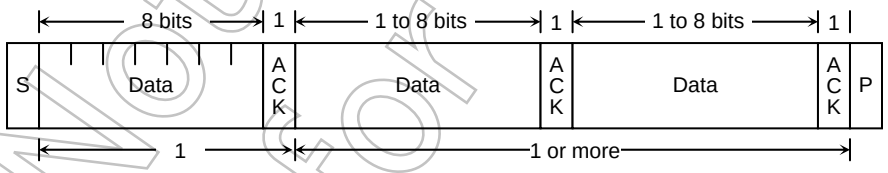
(a) Addressing format



(b) Addressing format (with restart)



(c) Free data format (data transferred from master device to slave device)



S: Start condition
R/$\overline{W}$: Direction bit
ACK: Acknowledge bit
P: Stop condition

Figure 3.10.3 Data Format in the I2C Bus Mode

3.10.4 I²C Bus Mode Control Register

The following registers are used to control and monitor the operation status when using the serial bus interface (SBI0, SBI1) in the I²C bus mode.

Serial Bus Interface 0 Control Register 1

		7	6	5	4	3	2	1	0
SBI0CR1 (1240H)	Bit symbol	BC2	BC1	BC0	ACK		SCK2	SCK1	SCK0/ SWRMON
	Read/Write	W			R/W		W		R/W
A read-modify-write operation cannot be performed.	Reset State	0	0	0	0		0	0	0/1 (Note 3)
	Function	Number of transferred bits (Note 1)			Acknowledge edge mode specification 0: Not generate 1:Generate		Internal serial clock selection and software reset monitor (Note 2)		

Internal serial clock selection <SCK2:0> at write

000	n = 5	– (Note 4)	System clock: f_{SYS}
001	n = 6	– (Note 4)	f_{SYS} = 20 MHz
010	n = 7	– (Note 4)	(internal SCL output)
011	n = 8	– (Note 4)	
100	n = 9	76.9 kHz	
101	n = 10	38.8 kHz	$f_{SCL} = \frac{f_{SYS} \times 2}{2^n + 8}$ [Hz]
110	n = 11	19.5 kHz	
111	Reserved	(Reserved)	

Software reset state monitor <SWRMON> at Read

0	During software reset
1	Initial data

Acknowledge mode specification

0	Not generate clock pulse for acknowledge signal
1	Generate clock pulse for acknowledge signal

Number of bits transferred

<BC2:0>	<ACK> = "0"		<ACK> = "1"	
	Number of clock pulses	Bits	Number of clock pulses	Bits
000	8	8	9	8
001	1	1	2	1
010	2	2	3	2
011	3	3	4	3
100	4	4	5	4
101	5	5	6	5
110	6	6	7	6
111	7	7	8	7

Note 1: Set the <BC2:0> to "000" before switching to a clocked-synchronous 8-bit SIO mode.

Note 2: For the frequency of the SCL pin clock, see 3.10.5 (3) "Serial clock".

Note 3: Initial data of SCK0 is "0", SWRMON is "1".

Note 4: This I²C bus circuit does not support Fast mode, it supports standard mode only. Although the I²C bus circuit itself allows the setting of a baud rate over 100 kbps, the compliance with the I²C specification is not guaranteed in that case.

Figure 3.10.11 Registers for the I^2C Bus Mode (SBI1)

3.10.5 Control in I²C Bus Mode

(1) Acknowledge mode specification

Set the SBI0CR1<ACK> to "1" for operation in the acknowledge mode. The TMP92CY23/CD23A generates an additional clock pulse for an acknowledge signal when operating in master mode. In the transmitter mode during the clock pulse cycle, the SDA0 pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during the clock pulse cycle, the SDA0 pin is set to the low in order to generate the acknowledge signal.

Clear the <ACK> to "0" for operation in the non-acknowledge mode. The TMP92CY23/CD23A does not generate a clock pulse for the acknowledge signal when operating in the master mode.

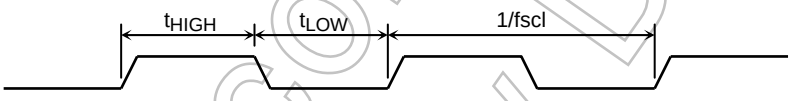
(2) Number of transfer bits

Since the SBI0CR1<BC2:0> is cleared to "000" on start up, a slave address and direction bit transmissions are executed in 8 bits. Other than these, the <BC2:0> retains a specified value.

(3) Serial clock

1. Clock source

The SBI0CR1<SCK2:0> is used to specify the maximum transfer frequency for output on the SCL pin in the master mode. Set the baud rates, which have been calculated according to the formula below, to meet the specifications of the I²C bus, such as the smallest pulse width of t_{LOW}.



$t_{LOW} = 2^{n-1}/f_{SBI}$

$t_{HIGH} = 2^{n-1}/f_{SBI} + 8/f_{SBI}$

$fscl = 1/(t_{LOW} + t_{HIGH})$

$= \frac{f_{SBI}}{2^n + 8}$

SBI0CR1<SCK2:0>	n
000	5
001	6
010	7
011	8
100	9
101	10
110	11

Note1: f_{SBI} shows f_{SYS}.

Note2: In a setup of prescaler of SYSCR0, the fc/16 mode cannot be used at the time of SBI circuit use.

Figure 3.10.12 Clock Source

2. Clock synchronization

In the I²C bus mode, in order to wired-AND a bus, a master device which pulls down a clock line to low level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

The TMP92CY23/CD23A has a clock synchronization function for normal data transfer even when more than one master exists on the bus.

The example explains the clock synchronization procedures when two masters simultaneously exist on a bus.

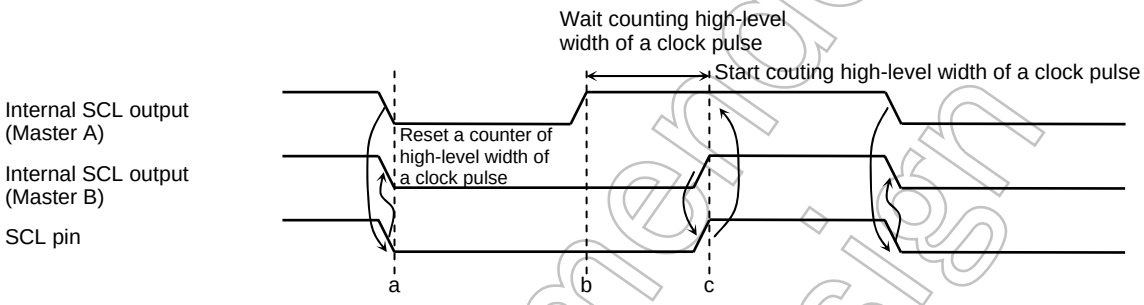


Figure 3.10.13 Clock Synchronization

As master A pulls down the internal SCL output to the low level at point "a", the SCL line of the bus becomes the low level. After detecting this situation, master B resets a counter of high-level width of an own clock pulse and sets the internal SCL output to the low level.

Master A finishes counting low-level width of an own clock pulse at point "b" and sets the internal SCL output to the high level. Since master B holds the SCL line of the bus at the low level, master A waits for counting high-level width of an own clock pulse. After master B finishes counting low-level width of an own clock pulse at point "c" and master A detects the SCL line of the bus at the high level, and starts counting high level of an own clock pulse. The clock pulse on the bus is determined by the master device with the shortest high-level width and the master device with the longest low-level width from among those master devices connected to the bus.

(4) Slave address and address recognition mode specification

When this device is to be used as a slave device, set the slave address <SA6:0> and <ALS> in I2C0AR.

Clear the <ALS> to "0" for the address recognition mode.

(5) Master/slave selection

Set the SBI0CR2<MST> to "1" for operating the TMP92CY23/CD23A as a master device. Clear the SBI0CR2<MST> to "0" for operation as a slave device. The <MST> is cleared to "0" by the hardware after a stop condition on the bus is detected or arbitration is lost.

(6) Transmitter/receiver selection

Set the SBI0CR2<TRX> to "1" for operating the TMP92CY23/CD23A as a transmitter. Clear the <TRX> to "0" for operation as a receiver. In slave mode, when transfer data in addressing format, when received slave address is same value with setting value to I2C0AR, or GENERAL CALL is received (All 8-bit data are "0" after a start condition), the <TRX> is set to "1" by the hardware if the direction bit (R/$\overline{W}$) sent from the master device is "1", and <TRX> is cleared to "0" by the hardware if the bit is "0".

In the master mode, after an acknowledge signal is returned from the slave device, the <TRX> is cleared to "0" by the hardware if a transmitted direction bit is "1", and is set to "1" by the hardware if it is "0". When an acknowledge signal is not returned, the current condition is maintained.

The <TRX> is cleared to "0" by the hardware after a stop condition on the bus is detected or arbitration is lost.

(7) Start/stop condition generation

When the SBI0SR<BB> = "0", slave address and direction bit which are set to SBI0DBR is output on the bus after generating a start condition by writing "1111" to the SBI0CR2<MST, TRX, BB, PIN>. It is necessary to set transmitted data to the data buffer register (SBI0DBR) and set "1" to the <ACK> beforehand.

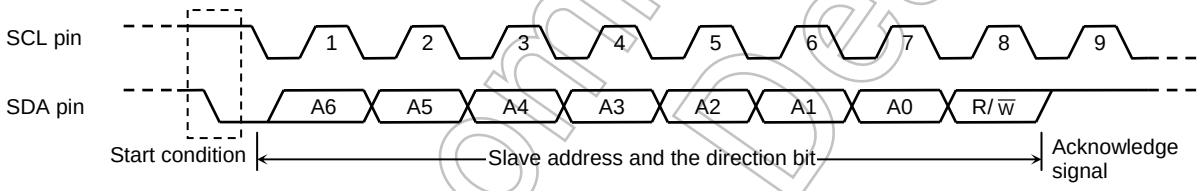

Figure 3.10.14 Start Condition Generation and Slave Address Generation

When the SBI0SR<BB> = "1", the sequence for generating a stop condition can be initiated by writing "111" to the SBI0CR2<MST, TRX, PIN> and writing "0" to the SBI0CR2<BB>. Do not modify the contents of the SBI0CR2<MST, TRX, BB, PIN> until a stop condition has been generated on the bus.

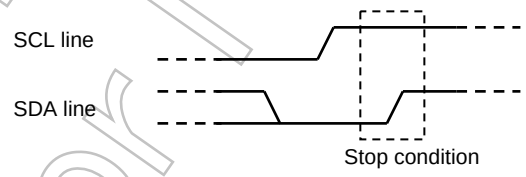

Figure 3.10.15 Stop Condition Generation

The state of the bus can be ascertained by reading the contents of SBI0SR<BB>. SBI0SR<BB> will be set to "1" (Bus busy status) if a start condition has been detected on the bus, and will be cleared to "0" if a stop condition has been detected (Bus free status).

In addition, since there is a restrictions matter about stop condition generating in master mode, please refer to 3.10.6. (4) "Stop condition generation".

(8) Interrupt service requests and interrupt cancellation

When a serial bus interface interrupt request 0 (INTSBE0) occurs, the SBI0SR2 <PIN> is cleared to "0". During the time that the SBI0SR2<PIN> is "0", the SCL line is pulled down to the low level.

The <PIN> is cleared to "0" when end of transmission or receiving 1 word of data. And when writing data to SBI0DBR or reading data from SBI0DBR, <PIN> is set to "1".

The time from the <PIN> being set to "1" until the SCL line is released takes t_{LOW}.

In the address recognition mode (<ALS> = "0"), <PIN> is cleared to "0" when the received slave address is the same as the value set at the I2C0AR or when a GENERAL CALL is received (All 8-bit data are "0" after a start condition). Although SBI0CR2<PIN> can be set to "1" by the program, the <PIN> is not clear it to "0" when it is programmed "0".

(9) Serial bus interface operation mode selection

The SBI0CR2<SBIM1:0> is used to specify the serial bus interface operation mode.

Set the SBI0CR2<SBIM1:0> to "10" when the device is to be used in I^2C bus mode after confirming pin condition of serial bus interface to "H".

Switch a mode to port after confirming a bus is free.

(10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on the bus in I^2C bus mode, a bus arbitration procedure has been implemented in order to guarantee the integrity of transferred data.

Data on the SDA pin is used for I^2C bus arbitration.

The following example illustrates the bus arbitration procedure when there are two master devices on the bus. Master A and master B output the same data until point "a". After master A outputs "L" and master B, "H", the SDA pin of the bus is wire-AND and the SDA pin is pulled down to the low level by master A. When the SCL pin of the bus is pulled up at point "b", the slave device reads the data on the SDA pin, that is, data in master A. Data transmitted from master B becomes invalid. The master B state is known as "ARBITRATION LOST". Master B device which loses arbitration releases the internal SDA output in order not to affect data transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

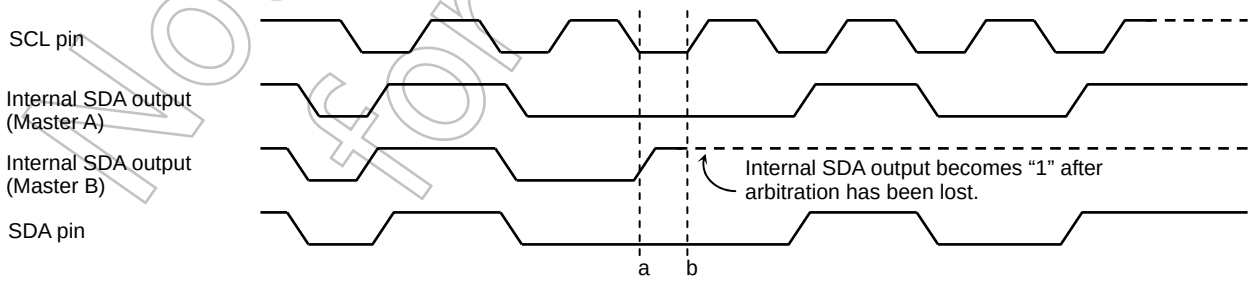

Figure 3.10.16 Arbitration Lost

The TMP92CY23/CD23A compares the levels on the bus's SDA line with those of the internal SDA output on the rising edge of the SCL line. If the levels do not match, arbitration is lost and SBI0SR<AL> is set to "1".

When SBI0SR<AL> is set to "1", SBI0SR<MST, TRX> are cleared to "00" and the mode is switched to slave receiver mode. Thus, clock output is stopped in data transfer after setting <AL> = "1".

SBI0SR <AL> is cleared to "0" when data is written to or read from SBI0DBR or when data is written to SBI0CR2.

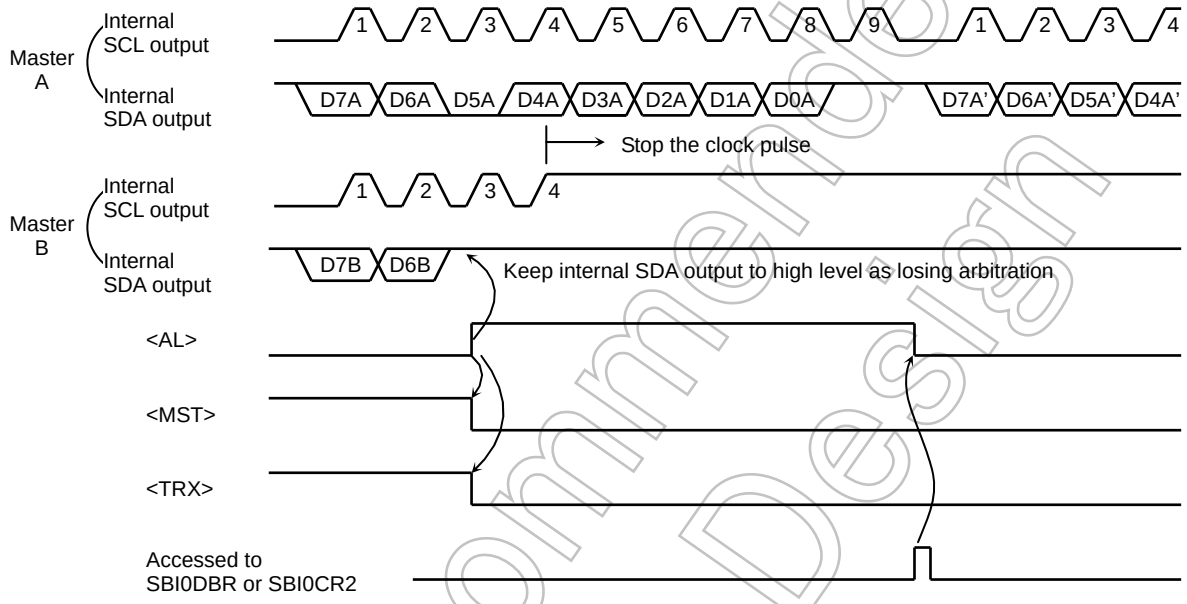

Figure3.10.17 Example of a Master Device B (D7A = D7B, D6A = D6B)

(11) Slave address match detection monitor

SBI0SR<AAS> operates following in during slave mode; In address recognition mode (e.g., when I2C0AR<ALS> = "0"), when received GENERAL CALL or same slave address with value set to I2C0AR, SBI0SR<AAS> is set to "1". When <ALS> = "1", SBI0SR<AAS> is set to "1" after the first word of data has been received. SBI0SR<AAS> is cleared to "0" when data is written to SBI0DBR or read from SBI0DBR.

(12) GENERAL CALL detection monitor

SBI0SR<AD0> operates following in during slave mode; when received GENERAL CALL (all 8-bit data is "0", after a start condition), SBI0SR<AD0> is set to "1". And SBI0SR<AD0> is cleared to "0" when a start condition or stop condition on the bus is detected.

(13) Last received bit monitor

The value on the SDA line detected on the rising edge of the SCL line is stored in the SBI0SR<LRB>. In the acknowledge mode, immediately after an INTSBE0 interrupt request has been generated, an acknowledge signal is read by reading the contents of the SBI0SR<LRB>.

(14) Software reset function

The software reset function is used to initialize the SBI circuit, when SBI is rocked by external noises, etc.

When write first "10" next "01" to SBI0CR2<SWRST1:0>, reset signal is inputted to serial bus interface circuit, and circuit is initialized. All command registers except SBI0CR2<SBIM1:0> and status flag except SBI0CR2<SBIM1:0> are initialized to value of just after reset. SBI0CR1<SWRMON> is set to "1" automatically when completed initialization of serial bus interface.

(15) Serial bus interface data buffer register (SBI0DBR)

The received data can be read and transmission data can be written by reading or writing SBI0DBR.

In the master mode, after the slave address and the direction bit are set in this register, the start condition is generated.

(16) I²C bus address register (I2C0AR)

I2C0AR<SA6:0> is used to set the slave address when the TMP92CY23/CD23A functions as a slave device.

The slave address outputted from the master device is recognized by setting the I2C0AR<ALS> to "0". And, the data format becomes the addressing format. When set <ALS> to "1", the slave address is not recognized, the data format becomes the free data format.

(17) Baud rate register (SBI0BR1)

Write "1" to baud rate circuit control register SBI0BR1<P4EN> before using I²C bus.

(18) Setting register for IDLE2 mode operation (SBI0BR0)

SBI0BR0<I2SBI0> is the register setting operation/stop during IDLE2 mode.
Therefore, setting <I2SBI0> is necessary before the HALT instruction is executed.

3.10.6 Data Transfer in I^2C Bus Mode

(1) Device initialization

In first, set the SBI0BR1<P4EN>, SBI0CR1<ACK, SCK2:0>. Set SBI0BR1<P4EN> to "1" and clear bits 7 to 5 and 3 in the SBI0CR1 to "0".

Next, set a slave address <SA6:0> and the <ALS> (<ALS> = "0" when an addressing format) to the I2C0AR.

And, write "000" to SBI0CR2<MST, TRX, BB>, "1" to <PIN>, "10" to <SBIM1:0> and "00" to <SWRST1:0>. Set initialization status to slave receiver mode by this setting.

(2) Start condition generation and slave address generation

1. Master mode

In the master mode, the start condition and the slave address are generated as follows.

In first, check a bus free status (when SBI0SR<BB> = "0").
Set the SBI0CR1<ACK> to "1" (Acknowledge mode) and specify a slave address and a direction bit to be transmitted to the SBI0DBR.

When SBI0SR<BB> = "0", the start condition are generated by writing "1111" to SBI0CR2<MST, TRX, BB, PIN>. Subsequently to the start condition, nine clocks are output from the SCL pin. While eight clocks are output, the slave address and the direction bit which are set to the SBI0DBR. At the 9th clock, the SDA line is released and the acknowledge signal is received from the slave device.

An INTSBE0 interrupt request generate at the falling edge of the 9th clock. The <PIN> is cleared to "0". In the master mode, the SCL pin is pulled down to the low level while <PIN> is "0". When an interrupt request is generated, the <TRX> is changed according to the direction bit only when an acknowledge signal is returned from the slave device.

2. Slave mode

In the slave mode, the start condition and the slave address are received.

After the start condition is received from the master device, while eight clocks are output from the SCL pin, the slave address and the direction bit that are output from the master device are received.

When a GENERAL CALL or the same address as the slave address set in I2C0AR is received, the SDA line is pulled down to the low level at the 9th clock, and the acknowledge signal is output.

An INTSBE0 interrupt request is generated on the falling edge of the 9th clock. The <PIN> is cleared to "0". In slave mode the SCL line is pulled down to the low level while the <PIN> = "0".

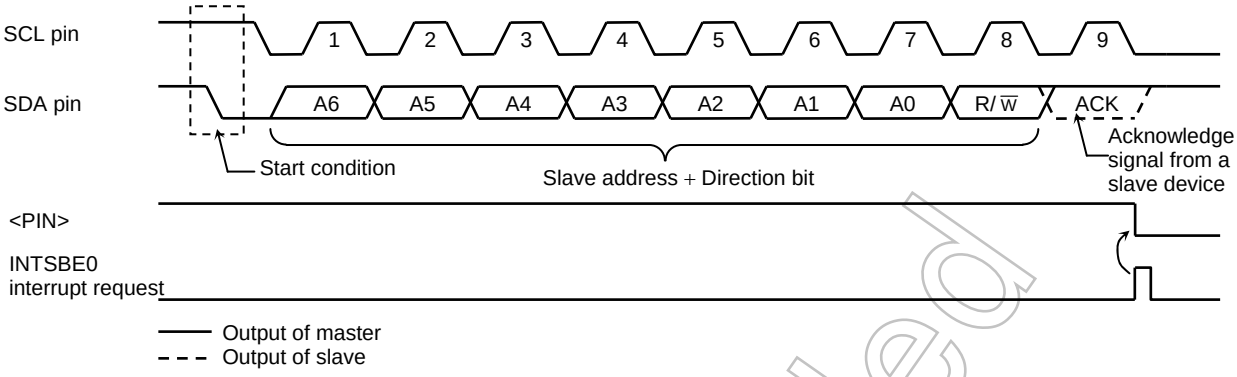

Figure3.10.18 Start Condition Generation and Slave Address Transfer

(3) 1-word data transfer

Check the <MST> by the INTSBE0 interrupt process after the 1-word data transfer is completed, and determine whether the mode is a master or slave.

1. If <MST> = "1" (Master mode)

Check the <TRX> and determine whether the mode is a transmitter or receiver.

When the <TRX> = "1" (Transmitter mode)

Check the <LRB>. When <LRB> is "1", a receiver does not request data. Implement the process to generate a stop condition (Refer to (4)) and terminate data transfer.

When the <LRB> is "0", the receiver is requests new data. When the next transmitted data is 8 bits, write the transmitted data to SBI0DBR. When the next transmitted data is other than 8 bits, set the <BC2:0> <ACK> and write the transmitted data to SBI0DBR. After written the data, <PIN> becomes "1", a serial clock pulse is generated for transferring a new 1-word of data from the SCL0 pin, and then the 1-word data is transmitted. After the data is transmitted, an INTSBE0 interrupt request generates. The <PIN> becomes "0" and the SCL0 line is pulled down to the low level. If the data to be transferred is more than one word in length, repeat the procedure from the <LRB> checking above.

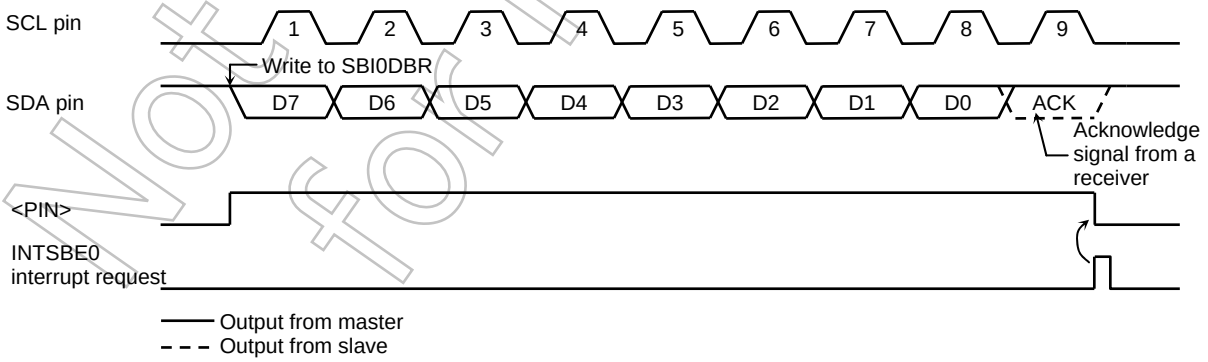

Figure3.10.19 Example in which <BC2:0> = "000" and <ACK> = "1" in Transmitter Mode

When the <TRX> is "0" (Receiver mode)

When the next transmitted data is other than 8 bits, set <BC2:0> <ACK> and read the received data from SBI0DBR to release the SCL0 line (Data which is read immediately after a slave address is sent is undefined). After the data is read, <PIN> becomes "1". Serial clock pulse for transferring new 1 word of data is defined SCL and outputs "L" level from SDA0 pin with acknowledge timing.

An INTSBE0 interrupt request then generates and the <PIN> becomes "0", Then the TMP92CY23/CD23A pulls down the SCL pin to the low level. The TMP92CY23/CD23A outputs a clock pulse for 1 word of data transfer and the acknowledge signal each time that received data is read from the SBI0DBR.

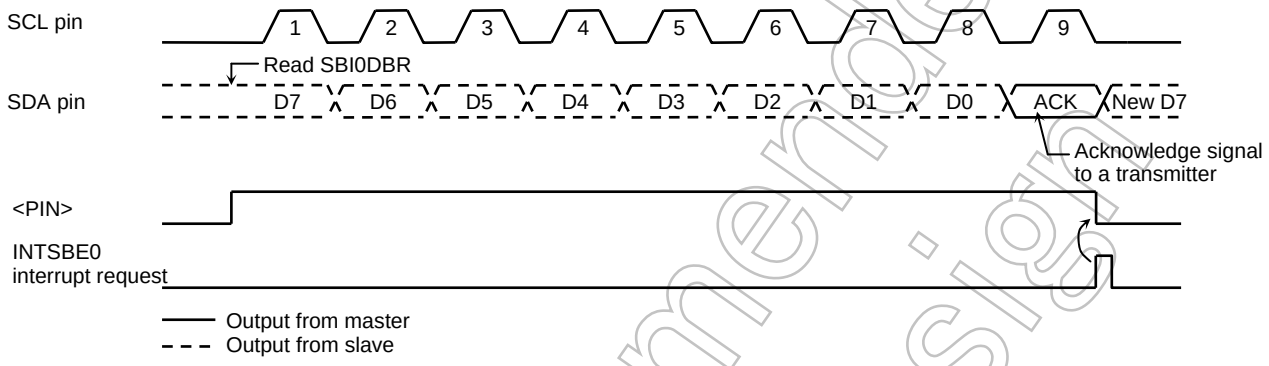

Figure3.10.20 Example of when <BC2:0> = "000", <ACK> = "1" in Receiver Mode

In order to terminate the transmission of data to a transmitter, clear <ACK> to "0" before reading data which is 1 word before the last data to be received. The last data word does not generate a clock pulse as the acknowledge signal. After the data has been transmitted and an interrupt request has been generated, set <BC2:0> to "001" and read the data. The TMP92CY23/CD23A generates a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA0 line on the bus remains high. The transmitter receives the high signal as an ACK signal. The receiver indicates to the transmitter that the data transfer is completed.

After the one data bit has been received and an interrupt request has been generated, the TMP92CY23/CD23A generates a stop condition (See section (4)) and terminates data transfer.

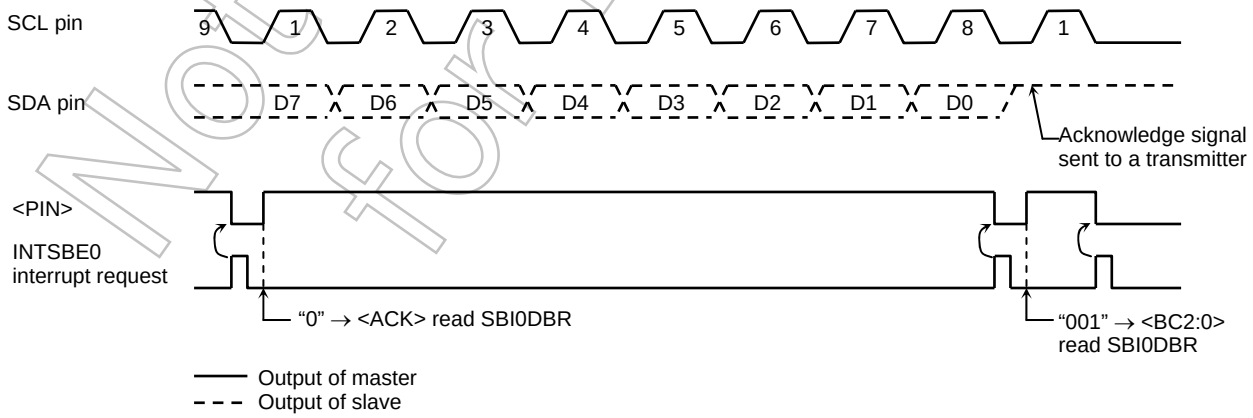

Figure3.10.21 Termination of Data Transfer in Master Receiver Mode

2. When the <MST> is "0" (Slave mode)

In the slave mode the TMP92CY23/CD23A operates either in normal slave mode or in slave mode after losing arbitration.

In the slave mode, an INTSBE0 interrupt request generate when the TMP92CY23/CD23A receives a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is completed, or after matching received address. In the master mode, the TMP92CY23/CD23A operates in a slave mode if it losing arbitration. An INTSBE0 interrupt request is generated when a word data transfer terminates after losing arbitration. When an INTSBE0 interrupt request is generated the <PIN> is cleared to "0" and the SCL pin is pulled down to the low level. Either reading/writing from/to the SBI0DBR or setting the <PIN> to "1" will release the SCL pin after taking t_{LOW} time.

Check the SBI0SR<AL>, <TRX>, <AAS>, and <AD0> and implements processes according to conditions listed in the next table.

Table 3.10.1 Operation in the Slave Mode

<TRX>	<AL>	<AAS>	<AD0>	Conditions	Process
1	1	1	0	The TMP92CY23/CD23A detects arbitration lost when transmitting a slave address, and receives a slave address for which the value of the direction bit sent from another master is “1”.	Set the number of bits of single word to <BC2:0>, and write the transmit data to SBI0DBR.
	0	1	0	In slave receiver mode, the TMP92CY23/CD23A receives a slave address for which the value of the direction bit sent from the master is “1”.	
		0	0	In salve transmitter mode, transmission of data of single word is terminated.	Check the <LRB>, If <LRB> is set to “1”, set <PIN> to “1”, reset “0” to <TRX> and release the bus for the receiver no request next data. If <LRB> was cleared to “0”, set bit number of single word to <BC2:0> and write the transmit data to SBI0DBR for the receiver requests next data.
0	1	1	1/0	The TMP92CY23/CD23A detects arbitration lost when transmitting a slave address, and receives a slave address or GENERAL CALL for which the value of the direction bit sent from another master is “0”.	Read the SBI0DBR for setting the <PIN> to “1” (Reading dummy data) or set the <PIN> to “1”.
		0	0	The TMP92CY23/CD23A detects arbitration lost when transmitting a slave address or data, and transfer of word terminates.	
	0	1	1/0	In slave receiver mode the TMP92CY23/CD23A receives a slave address or GENERAL CALL for which the value of the direction bit sent from the master is “0”.	
		0	1/0	In slave receiver mode the TMP92CY23/CD23A terminates receiving word data.	Set bit number of single word to <BC2:0>, and read the receiving data from SBI0DBR.

(4) Stop condition generation

When SBI0SR<BB> = "1", the sequence for generating a stop condition is started by writing "111" to SBI0CR2<MST, TRX, PIN> and "0" to SBI0CR2<BB>. Do not modify the contents of SBI0CR2<MST, TRX, PIN, BB> until a stop condition has been generated on the bus. When the bus's SCL line has been pulled low by another device, the TMP92CY23/CD23A generates a stop condition when the other device has released the

SCL line and SDA0 pin rising.

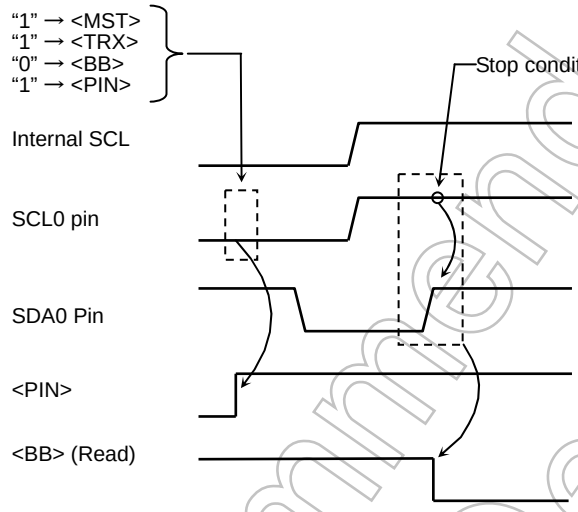

Figure3.10.22 Stop Condition Generation (Single master)

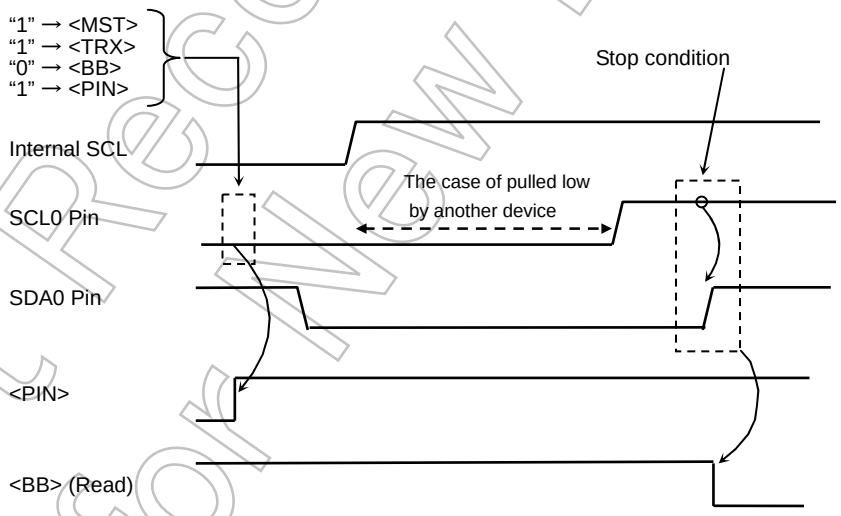

Figure3.10.23 Stop Condition Generation (Multi master)

(5) Restart

Restart is used during data transfer between a master device and a slave device to change the data transfer direction. The following description explains how to restart when this device is in the master mode.

Clear the SBI0CR2<MST, TRX, BB> to "000" and set the SBI0CR2<PIN> to "1" to release the bus. The SDA0 line remains the high level and the SCL0 pin is released. Since a stop condition is not generated on the bus, other devices assume the bus to be in a busy state. Check the SBI0SR<BB> until it becomes "0" to check that the SCL0 pin of this device is released. Check the <LRB> until it becomes "1" to check that the SCL line on a bus is not pulled down to the low level by other devices. After confirming that the bus stays in a free state, generate a start condition with procedure described in (2).

In order to meet setup time when restarting, take at least 4.7 μs of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

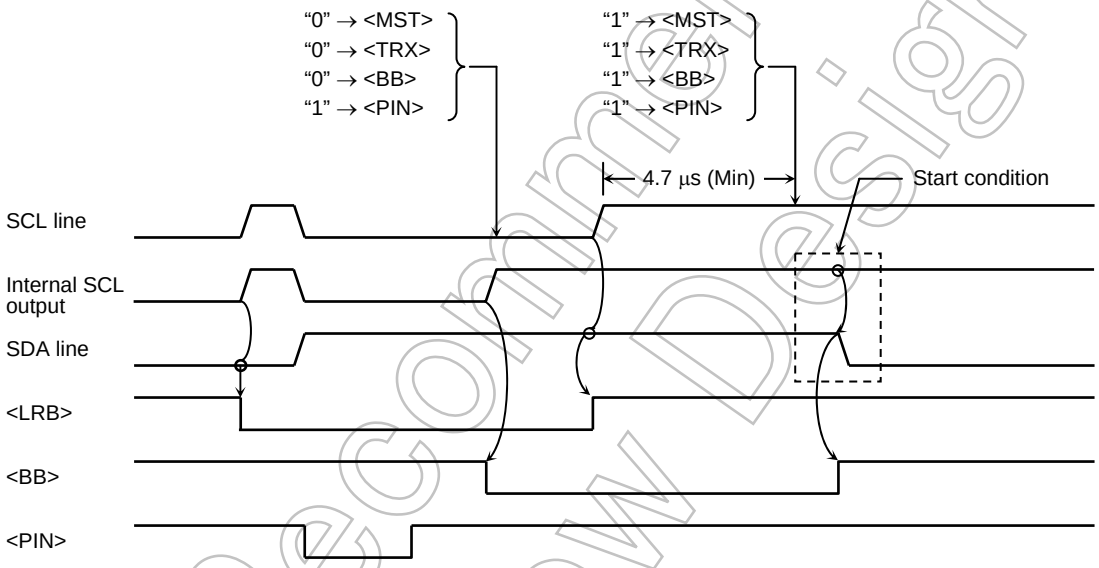

Figure 3.10.24 Timing Diagram when Restarting

3.10.7 Clocked-synchronous 8-Bit SIO Mode Control

The following registers are used to control and monitor the operation status when the serial bus interface (SBI) is being operated in clocked-synchronous 8-bit SIO mode.

Serial Bus Interface 0 Control Register 1

SBI0CR1 (1240H)

A read-modify-write operation cannot be performed.

Figure 3.10.28 Registers for the SIO Mode (SBI1)

(1) Serial clock

1. Clock source

SBI0CR1<SCK2:0> is used to select the following functions:

Internal clock

In an internal clock mode, any of seven frequencies can be selected. The serial clock is output to the outside on the SCK pin.

When the device is writing (in the transmit mode) or reading (in the receive mode) data cannot follow the serial clock rate, an automatic wait function is executed to stop the serial clock automatically and holds the next shift operation until reading or writing is complete.

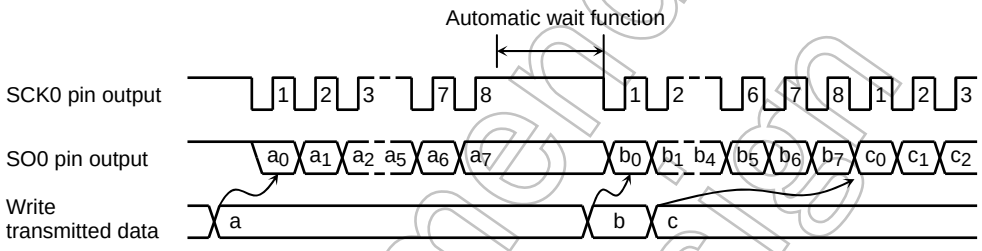

Figure 3.10.29 Automatic Wait Function

External clock (<SCK2:0> = "111")

An external clock input via the SCK pin is used as the serial clock. In order to ensure the integrity of shift operations, both the high and low-level serial clock pulse widths shown below must be maintained. The maximum data transfer frequency is 1.25 MHz (when f_{SYS} = 20 MHz).

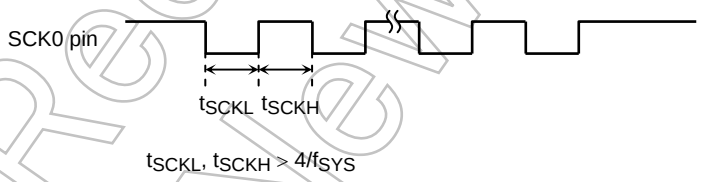

Figure 3.10.30 Maximum Data Transfer Frequency when External Clock Input

2. Shift edge

Data is transmitted on the leading edge of the clock and received on the trailing edge.

(a) Leading edge shift

Data is shifted on the leading edge of the serial clock (on the falling edge of the SCK pin input/output).

(b) Trailing edge shift

Data is shifted on the trailing edge of the serial clock (on the rising edge of the SCK pin input/output).

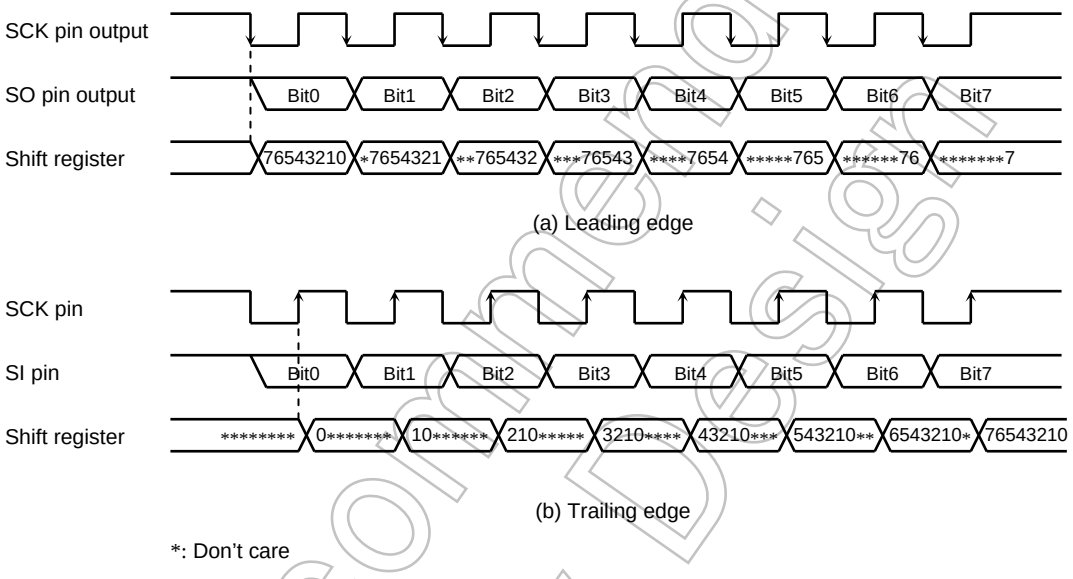

Figure 3.10.31 Shift Edge

(2) Transfer modes

The SBI0CR1<SIOM1:0> is used to select a transmit, receive or transmit/receive mode.

1. 8-bit transmit mode

Set a control register to a transmit mode and write transmission data to the SBI0DBR.

After the transmit data has been written, set the SBI0CR1<SIOS> to "1" to start data transfer. The transmitted data is transferred from the SBI0DBR to the shift register and output, starting with the least significant bit (LSB), via the SO pin and synchronized with the serial clock. When the transmission data has been transferred to the shift register, the SBI0DBR becomes empty. The INTSBE0 (Buffer empty) interrupt request is generated to request new data.

When the internal clock is used, the serial clock will stop and the automatic wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new transmission data is written, the automatic wait function is canceled.

When the external clock is used, data should be written to the SBI0DBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to the SBI0DBR by the interrupt service program.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO pin holds final bit of the last data until falling edge of the SCK.

Data transmission ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the <SIOINH> is set to "1". When the <SIOS> is cleared to "0", the transmitted mode ends when all data is output. In order to confirm whether data is being transmitted properly by the program, the <SIOF> (Bit3 of the SBI0SR) to be sensed. The SBI0SR<SIOF> is cleared to "0" when transmission has been completed. When the <SIOINH> is set to "1", transmitting data stops. The <SIOF> turns "0".

When the external clock is used, it is also necessary to clear the <SIOS> to "0" before new data is shifted; otherwise, dummy data is transmitted and operation ends.

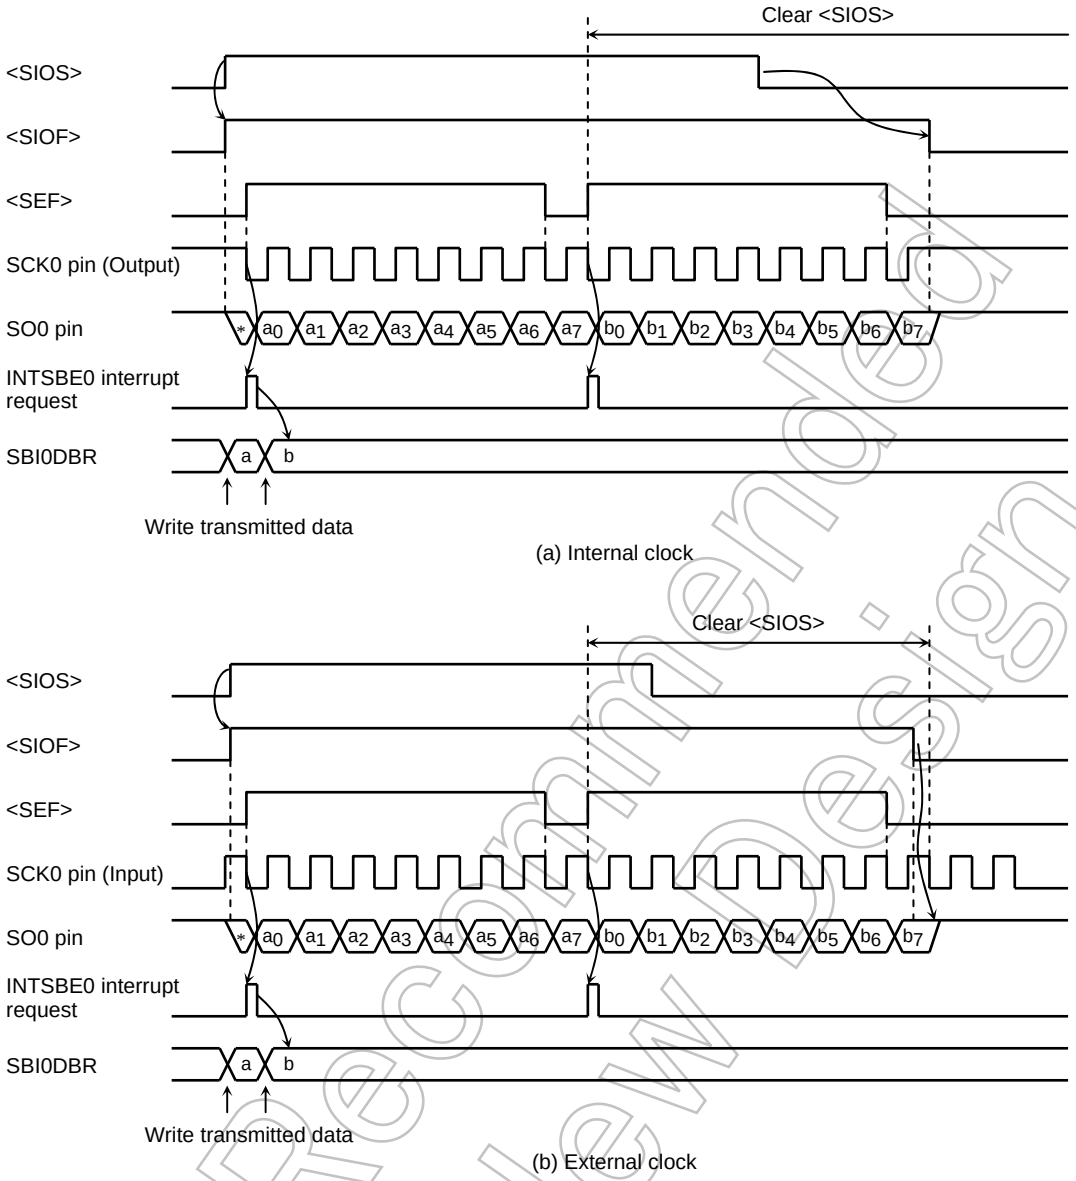

Figure 3.10.32 Transfer Mode

Example: Program to stop data transmission (when an external clock is used)

```
STEST1:   BIT   2, (SBI0SR)          ;   If <SEF> = “1” then loop
          JR    NZ, STEST1
STEST2:   BIT   0, (PN)              ;   If SCK0 = “0” then loop
          JR    Z, STEST2
          LD    (SBI0CR1), 00000111B   ;   <SIOS> ← “0”
```

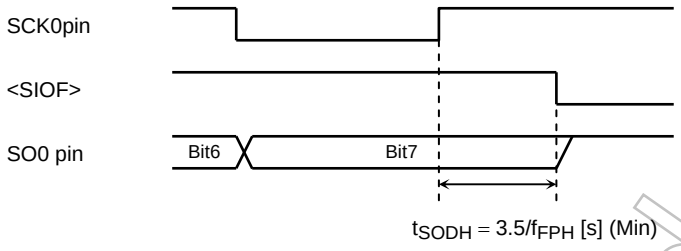

Figure 3.10.33 Transmitted Data Hold Time at End of Transmission

2. 8-bit receive mode

Set the control register to receive mode and set the SBI0CR1<SIOS> to "1" for switching to receive mode. Data is received into the shift register via the SI pin and synchronized with the serial clock, starting from the least significant bit (LSB). When the 8-bit data is received, the data is transferred from the shift register to the SBI0DBR. The INTSBE0 (Buffer full) interrupt request is generated to request that the received data be read. The data is then read from the SBI0DBR by the interrupt service program.

When the internal clock is used, the serial clock will stop and the automatic wait function will be in effect until the received data is read from the SBI0DBR.

When the external clock is used, since shift operation is synchronized with an external clock pulse, the received data should be read from the SBI0DBR before the next serial clock pulse is input. If the received data is not read, further data to be received is canceled. The maximum transfer speed when an external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when the received data is read.

Receiving of data ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the <SIOINH> is set to "1". If <SIOS> is cleared to "0", received data is transferred to the SBI0DBR in complete blocks. The received mode ends when the transfer is complete. In order to confirm whether data is being received properly by the program, the SBI0SR<SIOF> to be sensed. The <SIOF> is cleared to "0" when receiving is complete. When it is confirmed that receiving has been completed, the last data is read. When the <SIOINH> is set to "1", data receiving stops. The <SIOF> is cleared to "0". (The received data becomes invalid, therefore no need to read it.)

Note: When the transfer mode is changed, the contents of the SBI0DBR will be lost. If the mode must be changed, conclude data receiving by clearing the <SIOS> to "0", read the last data, then change the mode.

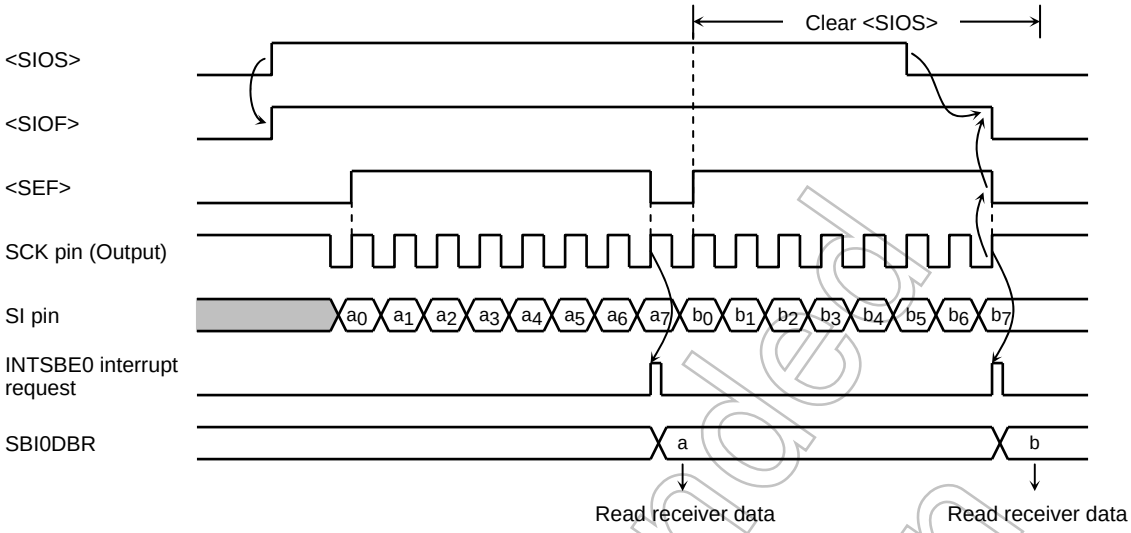

Figure 3.10.34 Receiver Mode (Example: Internal clock)

3. 8-bit transmit/receive mode

Set a control register to a transmit/receive mode and write data to the SBI0DBR. After the data is written, set the SBI0CR<SIOS> to "1" to start transmitting/receiving. When data is transmitted, the data is output from the SO0 pin, starting from the least significant bit (LSB) and synchronized with the leading edge of the serial clock signal. When data is received, the data is input via the SI pin on the trailing edge of the serial clock signal. 8-bit data is transferred from the shift register to the SBI0DBR and the INTSBE0 interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the data which is to be transmitted. The SBI0DBR is used for both transmitting and receiving. Transmitted data should always be written after received data is read.

When the internal clock is used, the automatic wait function will be in effect until the received data is read and the next data is written.

When the external clock is used, since the shift operation is synchronized with the external clock, the received data is read and transmitted data is written before a new shift operation is executed. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time at which received data is read and transmitted data is written.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO pin holds final bit of the last data until falling edge of the SCK.

Transmitting/receiving data ends when the <SIOS> is cleared to "0" by the INTSBE0 interrupt service program or when the SBI0CR1<SIOINH> is set to "1". When the <SIOS> is cleared to "0", received data is transferred to the SBI0DBR in complete blocks. The transmit/receive mode ends when the transfer is complete. In order to confirm whether data is being transmitted/received properly by the program, set the SBI0SR to be sensed. The <SIOF> is set to "0" when transmitting/receiving is completed. When the <SIOINH> is set to "1", data transmitting/receiving stops. The <SIOF> is then cleared to "0".

Note: When the transfer mode is changed, the contents of the SBI0DBR will be lost. If the mode must be changed, conclude data transmitting/receiving by clearing the <SIOS> to "0", read the last data, then change the transfer mode.

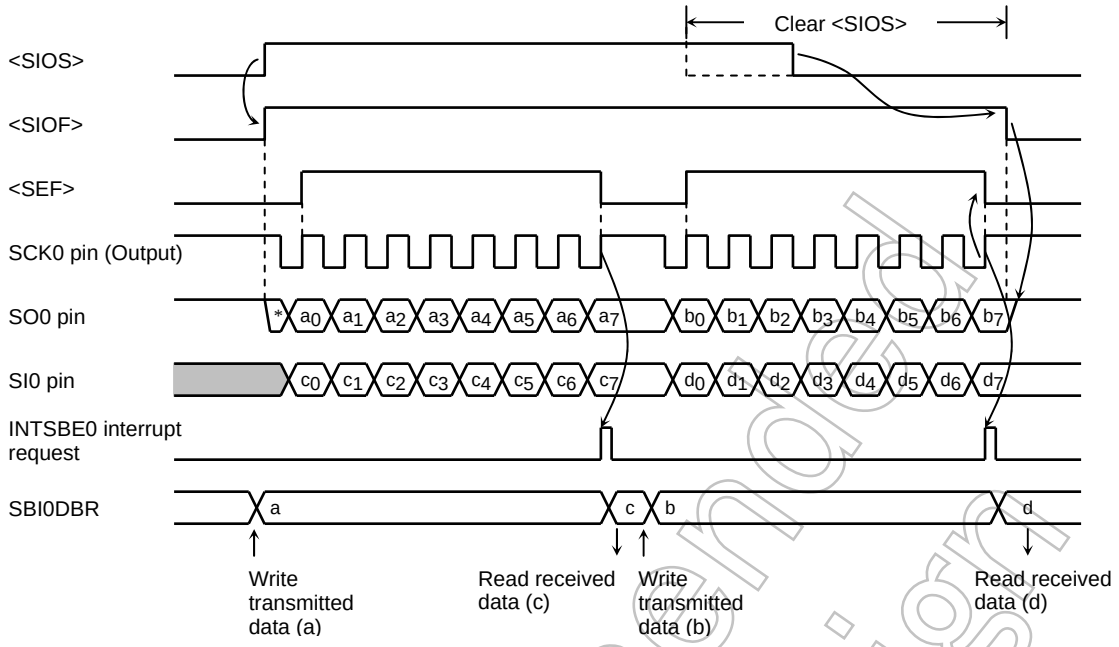

Figure 3.10.35 Transmit/Received Mode (Example: Internal clock)

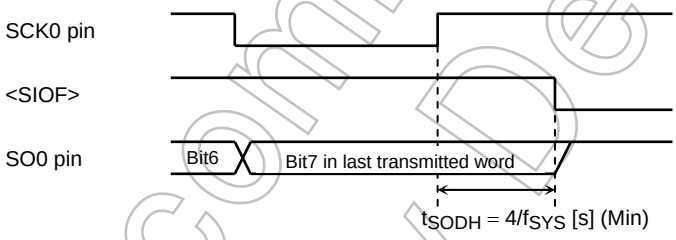

Figure 3.10.36 Transmitted Data Hold Time at End of Transmit/Receive

3.11 High Speed SIO (HSC)

Multifunction High Speed SIO (HSC) for 1 channel is contained (Note). HSC supports only the master mode in I/O interface mode (synchronous transmission).

Note: HSC circuit is not built into TMP92CY23.

Its features are summarized as follows:

1) Double buffer (Transmit/Receive)
2) Generates the CRC-7 and CRC-16 values for transmission and reception
3) Baud Rate : 10Mbps (max)
4) Selects the MSB/LSB-first
5) Selects the 8/16-bit data length
6) Selects the Clock Rising/Falling edge
7) One types of interrupt: INTHSC

Select Read/Mask/Clear interrupt/Clear enable for 4 interrupts:
RFR0 (Receive buffer of HSC0RD: Full),
RFW0 (Transmission buffer of HSC0TD: Empty),
REND0 (Receive buffer of HSC0RS: Full),
TEND0 (Transmission buffer of HSC0TS: Empty).
RFR0,RFW0 can be processed data at high-speeed by using micro DMA.

Table 3.11.1 Registers and Pins for HSC

	HSC
Pin name	HSSO (PF3) HSSI (PF4) HSCLK (PF5)

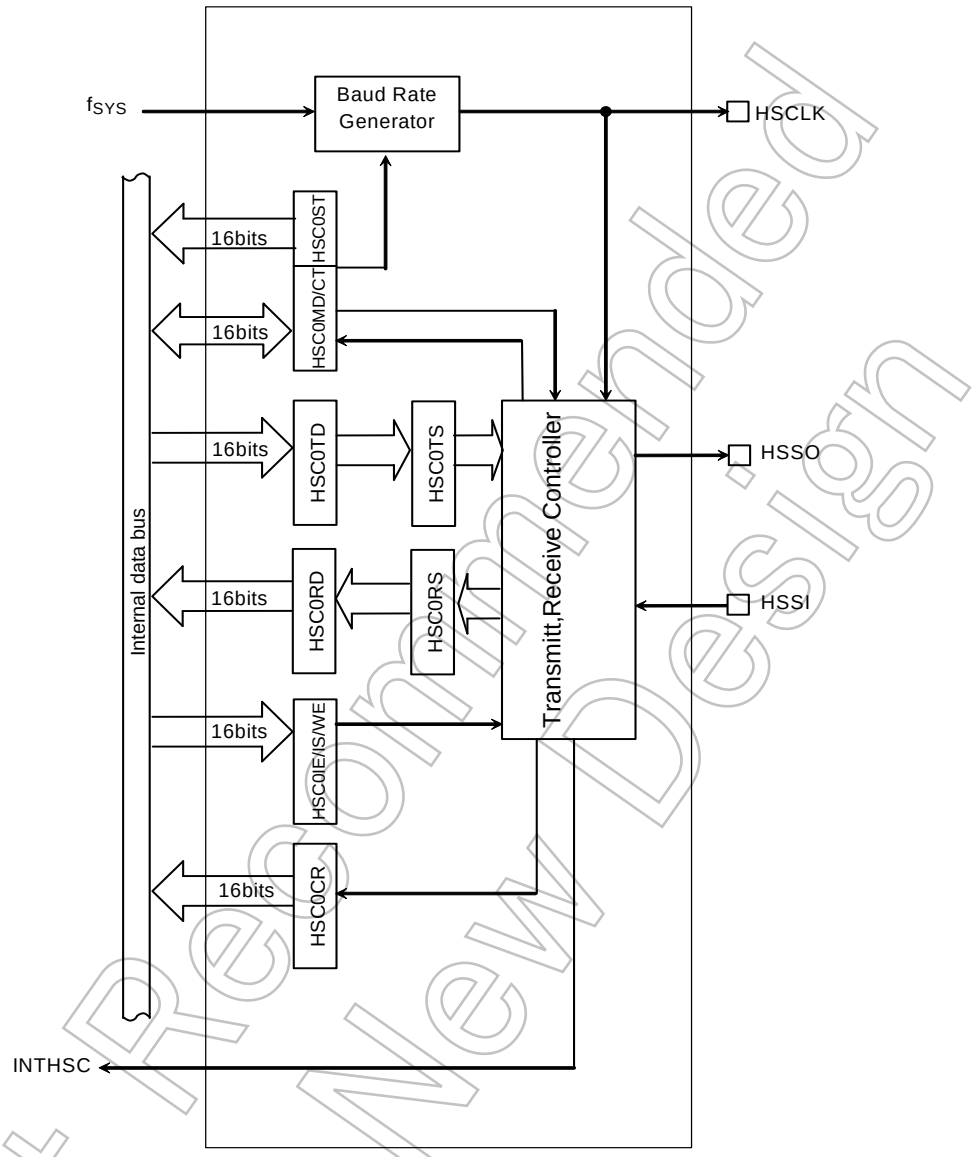
3.11.1 Block diagram

Figure 3.11.1 shows a block diagram of the HSC.



Note : The HSSO, HSSI, HSCLK pins are set to configured as input ports (Ports PF3, PF4 and PF5) by upon reset. Thus, these pins require pull-up resistors to fix their voltage levels.

Figure 3.11.1 HSC Block diagram

3.11.2 SFR

This section describes the SFRs of the HSC are as follows. These area connected to the CPU with 16 bit data buses.

(1) Mode setting register

The HSC0MD register specifies the operating mode, clock operation, etc.

HSC0MD Register

		7	6	5	4	3	2	1	0
HSC0MD (0C00H)	bit Symbol		XEN0				CLKSEL02	CLKSEL01	CLKSEL00

Figure 3.11.2 HSC0MD Register

(a) <LOOPBACK0>

The internal HSSO output to be internally connected to the HSSI input. This setup can be used for testing.

Also, a clock signal is generated from the HSCLK pin, regardless of whether data transmission or reception is in progress when setting the XEN0 and LOOPBACK0 bits to "1" enables.

Data transmission or reception must not be performed while changing the state of this bit.

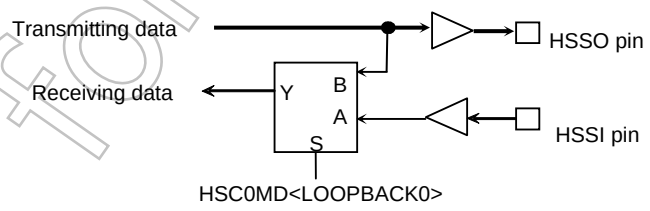

Figure 3.11.3 <LOOPBACK0> Register Function

(b) <MSB1ST0>

This bit specifies whether to transmit/receive byte with the MSB first or with the LSB first. Data transmission or reception must not be performed while changing the state of this bit.

(c) <DOSTAT0>

This bit specifies the status of the HSSO pin of when data transmission is not performed (i.e., after completing data transmission or during data reception). Data transmission or reception must not be performed while changing the state of this bit.

(d) <TCPOL0>

This bit specifies the polarity of the active edge of the synchronization clock for data transmission.

The XEN0 bit should be cleared to "0" for changing the state of this bit. At the same time, RCPOL0 should also be cleared to "0".

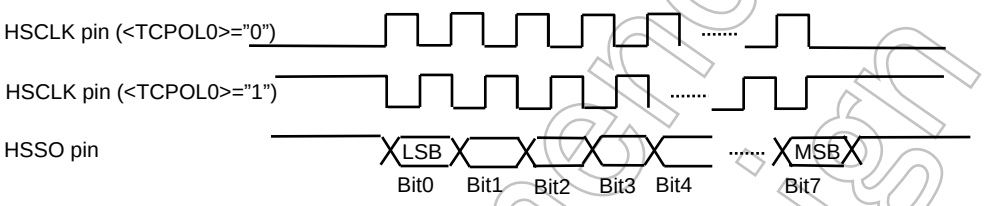

Figure 3.11.4 <TCPOL0> Register function

(e) <RCPOL0>

This bit specifies the polarity of the active edge of the synchronization clock during for data reception.

The <XEN0> bit should be cleared to "0" for changing the state of this bit. TCPOL0 should also be cleared to "0".

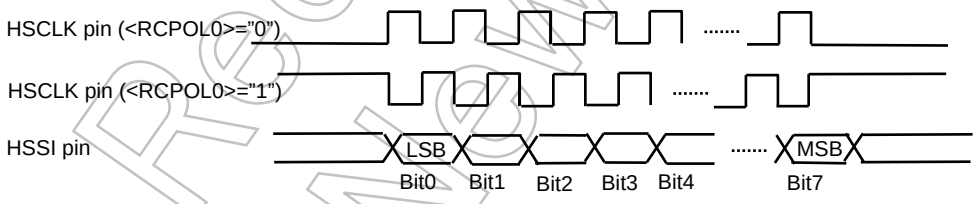

Figure 3.11.5 <RCPOL0> Register function

(f) <TDINV0>

This bit specifies whether to logically invert the data transmitted from the HSSO pin or not. Data transmission or reception must not be performed while changing the state of this bit.

Data which is inputted to CRC calculation circuit is transmission data which is written to HSC0TD. This input data is not corresponded to <TDINV0>.

<TDINV0> is not corresponded to <DOSTAT0>: it set condition of HSSO pin when it is not transferred.

(g) <RDINV0>

This bit specifies whether to logically invert the data received from the HSSI pin or not. Data transmission or reception must not be performed while changing the state of this bit.

Data which is inputted to CRC calculation circuit is selected by <RDINV0>.

(h) <XEN0>

This bit enables or disables the internal clock signal.

(i) <CLKSEL02:00>

This bit selects the baud rate. The baud rate is generated using the system clock f_{SYS} and is programmable as shown below according to the system clock settings.

Data transmission or reception must not be performed while changing the state of these bits

Table 3.11.2 Example of baud rate

<CLKSEL02:00>	Baud rate [Mbps]		
	f_{SYS} =12MHz	f_{SYS} =16MHz	f_{SYS} =20MHz
$f_{SYS}/2$	6	8	10
$f_{SYS}/4$	3	4	5
$f_{SYS}/8$	1.5	2	2.5
$f_{SYS}/16$	0.75	1	1.25
$f_{SYS}/32$	0.375	0.5	0.625
$f_{SYS}/64$	0.1875	0.25	0.3125

(2) Control Register

The HSC0CT register specifies data length, CRC, etc.

HSC0CT Register

		7	6	5	4	3	2	1	0
HSC0CT (0C02H)	bit Symbol	–	–	UNIT160			ALGNEN0	RXWEN0	RXUEN0
	Read/Write	R/W					R/W

Figure 3.11.6 HSC0CT Register

(a) <CRC16_7_B0>

This bit selects the CRC calculation algorithm from the CRC7 and CRC16.

(b) <CRCRX_TX_B0>

This bit selects the data to be sent to the CRC generator.

(c) <CRCRESET_B0>

This bit is used to initialize the CRC calculation register.

This section describes how to calculate the CRC16 of the transmit data and to append the calculated CRC value at the end of the transmit data. Figure 3.11.7 below illustrates the flow chart of the CRC calculation procedures.

a. Program the HSC0CT<CRC16_7_B> bit to select the CRC algorithm from CRC7 and CRC16. Then, also program the CRCRX_TX_B bit to specify the data on which the CRC calculation is performed.
b. To reset the HSC0CR register, write "0" to the CRCRESET_B bit and then write "1" to the same bit.
c. Load the HSC0TD register with the transmit data, and wait until transmission of all data is completed.
d. Read the HSC0CR register and obtain the result of the CRC calculation.
e. Transmit the CRC obtained in step (d) in the same way as step (c).

The CRC calculation on the receive data can be performed in the same procedures.

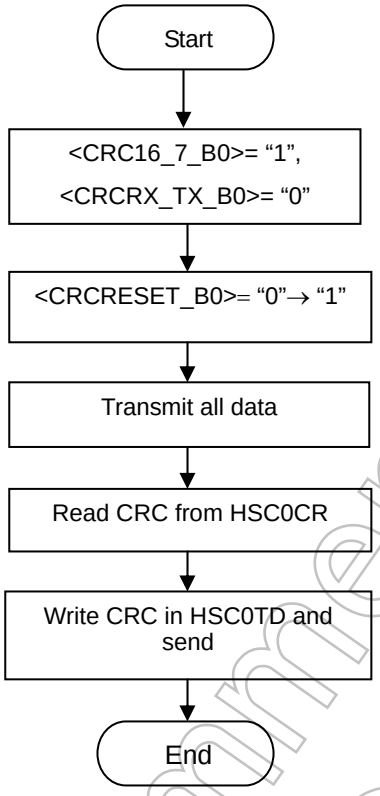

Figure 3.11.7 Flow Chart of the CRC Calculation Procedures

(d) <DMAERFW0>

This bit sets the interrupt clearing using to unnecessary because be supported RFW0 interrupt to Micro DMA. If this bit is set to “1”, it is set to one-shot interrupt, clearing interrupt by HSC0WE register become to unnecessary. HSC0ST<RFW0> flag generate 1-shot interrupt when change from “0” to “1”(Rising).

(e) <DMAERFR0>

This bit sets the interrupt clearing using CPU to unnecessary because be supported RFR0 interrupt to Micro DMA. If this bit is set to “1”, it is set to one-shot interrupt, clearing interrupt by HSC0WE register become to unnecessary. HSC0ST<RFR0> flag generate 1-shot interrupt when change from “0” to “1”(Rising).

(f) <UNIT160>

This bit selects the data length for transmission and reception. The data length is hereafter referred to as the UNIT. Data transmission or reception must not be performed while changing the state of this bit

(g) <ALGNEN0>

This bit should be set to “1” when performing the full-duplex communication. This bit specifies whether to align the transmit and receive data on the UNIT-size boundaries.

Data transmission or reception must not be performed while changing the state of this bit.

(h) <RXWEN0>

This bit enables or disables the Sequential mode reception.

(i) <RXUEN0>

This bit enables or disables the Unit mode reception.

For <RXWEN0> = "1", this bit is disabled. Data transmission or reception must not be performed while changing the state of this bit.

[Data Transmission/Reception Modes]

This HSC Controller supports six operating modes as listed below.

These are specified by the <ALGNEN0>, <RXWEN0>, <RXUEN0> bits.

Table 3.11.3 transmit/receive operation mode

Operation mode	Bit Settings			Description
	<ALGNEN0>	<RXWEN0>	<RXUEN0>	
(1) UNIT transmission	0	0	0	Transmit written data per UNIT
(2) Sequential transmission	0	0	0	Transmit written data sequentially
(3) UNIT reception	0	0	1	Receive only one UNIT-size data
(4) Sequential reception	0	1	0	Automatically receive data if buffer has any empty space
(5) UNIT transmission and reception	1	0	1	Transmit/receive one UNIT-size data with the addresses of transmit/receive data aligned on UNIT-size boundaries
(6)Sequential transmission and reception	1	1	0	Transmit/receive data sequentially with the addresses of transmit/receive data aligned on UNIT-size boundaries

Difference between the UNIT-mode and Sequential-mode transmission

UNIT mode transmission transmits one-UNIT by writing data after confirming HSC0ST<TEND0> = "1".

In the Sequential-mode transmission, transmit data written into the HSC0TD is loaded sequentially.

In hard ware, this mode of transmission keeps transmitting data as long as the transmit data exists. This mode of transmission keeps transmitting data as long as the transmit data exists. Therefore, the Sequential-mode transmission continues as long as the next data is written to it when HSC0ST<REND0> = "1".

Unit-mode transmission and Sequential-mode transmission depend on the way of using. Hardware doesn't depend on.

Figure 3.11.8 show Flow chart of UNIT-mode transmission and Sequential-mode transmission.

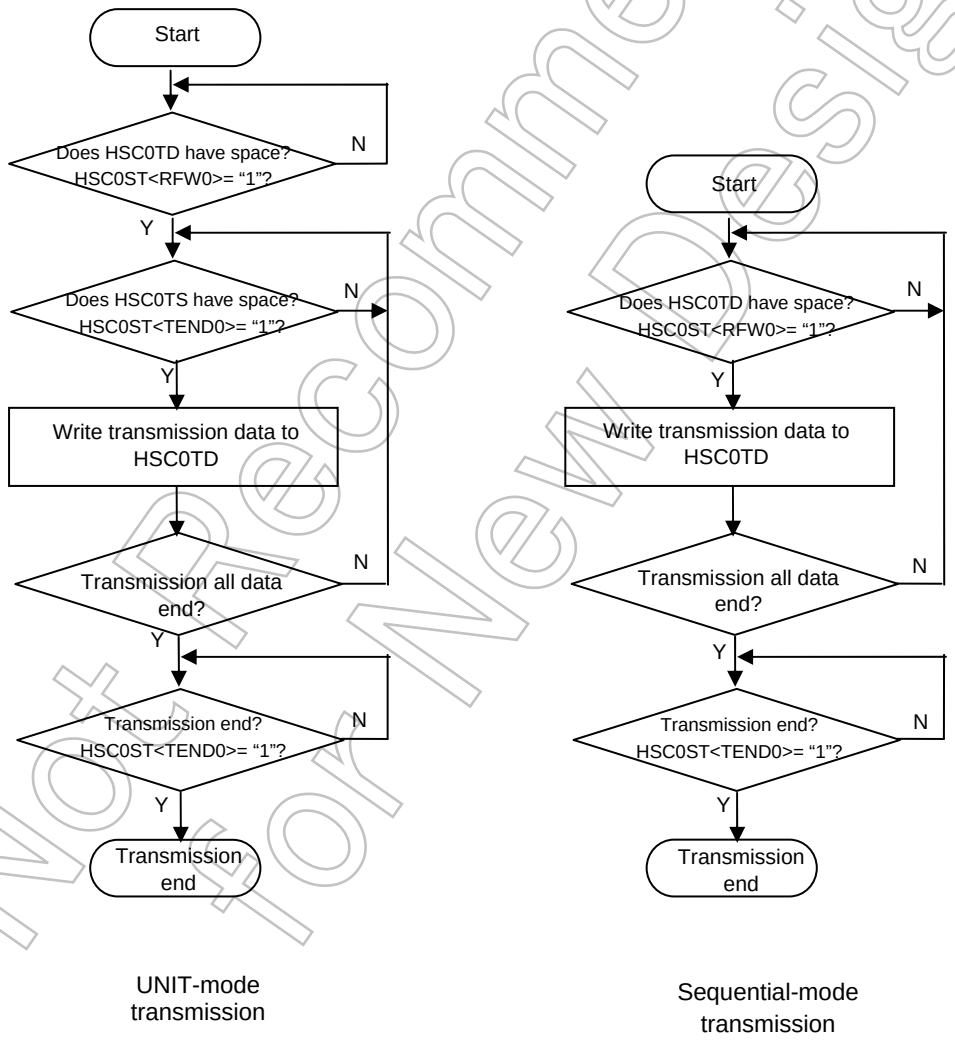

Figure 3.11.8 Flow chart of UNIT-mode transmission and Sequential-mode transmission

Differences Between the UNIT-mode and Sequential-mode Receptions

The UNIT-mode reception receives only one UNIT-size data.

Writing "1" to the HSC0CT<RXUEN0> bit initiates a receive operation of one UNIT data. Then, it is stored the received data into the receive data register (HSC0RD).

Reading the HSC0RD register after writing "0" to the HSC0CT<RXUEN0> bit.

If the HSC0RD register is read again when the HSC0CT<RXUEN0> bit is set to "1", one-UNIT data is additionally received.

In hardware, this mode receives sequentially by Single buffer.

HSC0ST<REND0> is changed during UNIT receiving.

The Sequential-mode reception automatically receives the data as long as the receive Buffer has any empty space.

This mode of reception keeps receiving the next data automatically unless the data receive Buffer becomes full. Therefore, the reception continues sequentially without stopping at every UNIT-sized reception by reading it after data is loaded in HSC0RD.

In hardware, this mode receives sequentially by Double buffer.

Figure 3.11.9 show Flow chart of UNIT-reception and Sequential-mode reception.

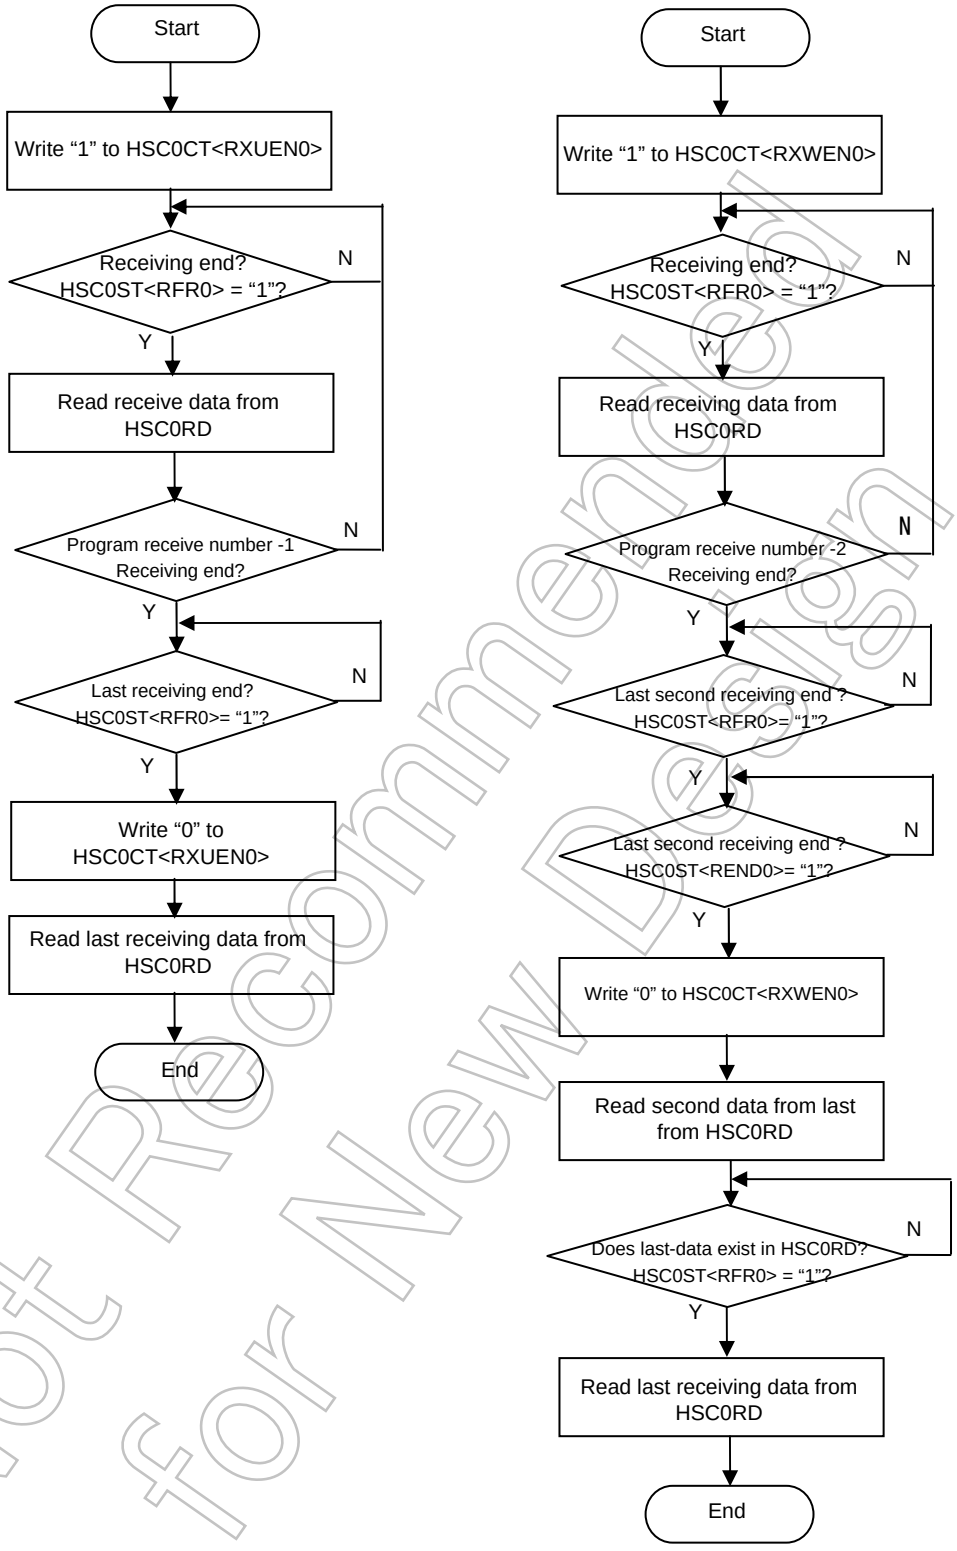

Figure 3.11.9 Flow chart of UNIT-mode reception and Sequential-mode reception

(3) Interrupt , Status register

Read of condition, Mask of condition, Clear interrupt and Clear enable can control each 4 interrupts; RFR0 (HSC0RD receiving buffer is full), RFW0 (HSC0TD transmission buffer is empty), REND0 (HSC0RS receiving buffer is full), TEND0 (HSC0TS transmission buffer is empty).

RFR0, RFW0 can high-speed transaction by micro DMA.

Following is description of Interrupt・status (example RFW0).

Status register HSC0ST<RFW0> show RFW0 (internal signal that show whether transmission data register exist or not). This register is "0" when transmission data exist. This register is "1" when transmission data doesn't exist. It can read internal signal directly. Therefore, it can confirm transmission data at any time.

Interrupt status register HSC0IS<RFWIS0> is set by rising edge of RFW0. This register keeps that condition until write "1" to this register and reset when HSC0WE<RFWWE0> is "1".

RFW0 interrupt generate when interrupt enable register HSC0IE<RFWIE0> is "1". When it is "0", interrupt is not generated.

Interrupt request register HSC0IR<RFWIR0> show whether interrupt is generating or not.

Interrupt status write enable register HSC0WE<RFWWE0> set that enables reset for reset interrupts status register by mistake.

Circuit config of transmission data shift register (HSC0TS), receiving register (HSC0RD), receiving data shift register (HSC0RS) are same with above register.

Control register HSC0CT<DMAERFW0>, HSC0CT<DMAERFR0> is register for using micro DMA. When micro DMA transfer is executed by using RFW0 interrupt, set "1" to <DMAERFW0>, and when it is executed by using RFR0 interrupt, set "1" to <DMAERFR0>, and prohibit other interrupt.

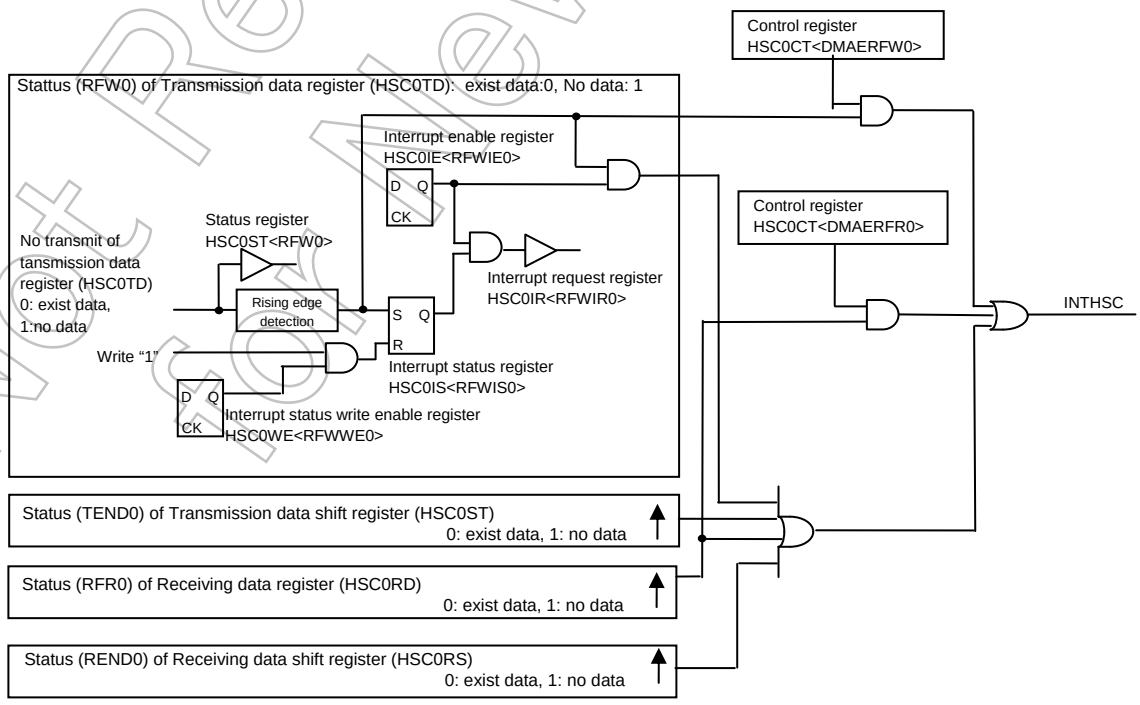

Figure 3.11.10 Figurer for interrupt, status

(3-1) Status register

This register contains four bits that indicates the status of data communication.

HSC0ST Register

		7	6	5	4	3	2	1	0
HSC0ST (0C04H)	bit Symbol					TEND0	REND0	RFW0	RFR0
	Read/Write					R			
	Reset State					1	0	1	0
	Function					Receiving 0:operation 1: no operation	Receive Shift register 0: no data 1: exist data	Transmit buffer 0:untransm -itted data exist 1: no Untrans-mitted data	Receive buffer 0:no valid data 1: valid data exist
		15	14	13	12	11	10	9	8
(0C05H)	bit Symbol								
	Read/Write								
	Reset State								
	Function								

Figure 3.11.11 HSC0ST Register

(a) <TEND0>

This bit is cleared to "0" when the transmit register (HSC0TS) contains valid data; otherwise, it is set to "1".

(b) <REND0>

This bit is set to "1" when completing the data reception and valid data is stored into the receive data register (if there is any valid data). This bit is cleared to "0" when the receive register (HSC0RS) contains no valid data, or when the reception is in progress.

It is cleared to "0", when CPU read the data and shift to receive read register.

(c) <RFW0>

After wrote the received data to receive data write register, shift the data to receive data shift register. This bit keeps "0"until all valid data has moved. And this bit is set to "1" when it can accept the next data and contains no valid data.

(d) <RFR0>

This bit is set to "1" when received data is shifted from received data shift register to received data read register and there is any valid data. It is set to "0" when the data is read and contains no valid data.

(3-2) Interrupt status register

This register is used for reading four interrupts status and clearing interrupts.

This register is cleared to "0" by writing "1" to applicable bit. Status of this register show interrupt source state. This register can confirm changing of interrupt condition, even if interrupt enable register is masked.

HSC0IS Register

		7	6	5	4	3	2	1	0
HSC0IS (0C08H)	bit Symbol					TENDIS0	RENDIS0	RFWIS0	RFRIS0

	Function								

Figure 3.11.12 HSC0IS Register

(a) <TENDIS0>

This bit is used for reading the status of TEND interrupt and clearing interrupt.
If writing this bit, set "1" to HSC0WE<TENDWE0>.

(b) <REMDIS0>

This bit is used for reading the status of REND interrupt and clearing interrupt.
If writing this bit, set "1" to HSC0WE<RENDWE0>.

(c) <RFWDIS0>

This bit is used for reading the status of RFW interrupt and clearing interrupt.
If writing this bit, set "1" to HSC0WE<RFWWE0>.

(d) <RFRIS0>

This bit is used for reading the status of RFR interrupt and clearing interrupt.
If writing this bit, set "1" to HSC0WE<RFRWE0>.

(3-3) Interrupt status write enable register

This register enables or disables the clearing status bit of four types of interrupts.

HSC0WE Register

		7	6	5	4	3	2	1	0
HSC0WE (0C0AH)	bit Symbol					TENDWE0	RENDWE0	RFWWE0	RFRWE0

		15	14	13	12	11	10	9	8
(0C07H)	bit Symbol	CRCD015	CRCD014	CRCD013	CRCD012	CRCD011	CRCD010	CRCD009	CRCD008
	Read/Write	R							
	Reset State	0	0	0	0	0	0	0	0
	Function	CRC calculation result load register [15:8]							

Figure 3.11.16 HSC0CR register

(a) <CRCD015:000>

The CRC result which is calculated according to the settings of the CRC16_7_b0, CRCRX_TX_B0 and CRCRESET_B0 bits in the HSC0CT register are loaded into this register. When using the CRC16 algorithm, all the bits participate in the CRC generation. When using the CRC7 algorithm, only the lower seven bits participates in the CRC generation. The following describes the steps required to calculate the CRC16 for the transmit data.

First, initialize the CRC calculation register by writing "1" to the CRCRESET_B0 bit after programming three bits as follows: CRC16_7_b0 = "1", CRCRX_TX_B0 = "0", and CRCRESET_B0 = "0".

Then, by writing the transmit data into the HSC0TD register, complete the transmission of all bits, for which the CRC should be calculated.

The HSC0ST<TEND0> bit should be checked to confirm whether the reception is completed.

By reading the HSC0CR register after the transmission is completed, the CRC16 for the transmit data can be obtained.

(5) Transmit Data Register

This register is used for writing the transmit data.

HSC0TD Register

		7	6	5	4	3	2	1	0
HSC0TD (0C10H)	bit Symbol	TXD007	TXD006	TXD005	TXD004	TXD003	TXD002	TXD001	TXD000
	Read/Write	R/W							
	Reset State	0	0	0	0	0	0	0	0

	function	Receive data shift register [15:8]							

Figure 3.11.20 HSC0RS Register

(a) <RSD015:000>

This register is used for reading the status of receive data shift register.

HSC0CT<UNIT160> = "1", all bits are valid.

HSC0CT<UNIT160> = "0", lower 7 bits are valid.

3.11.3 Operation timing

Following examples show operation timing.

- Setting condition 1:

  Transmission in UNIT=8bit, LSB first

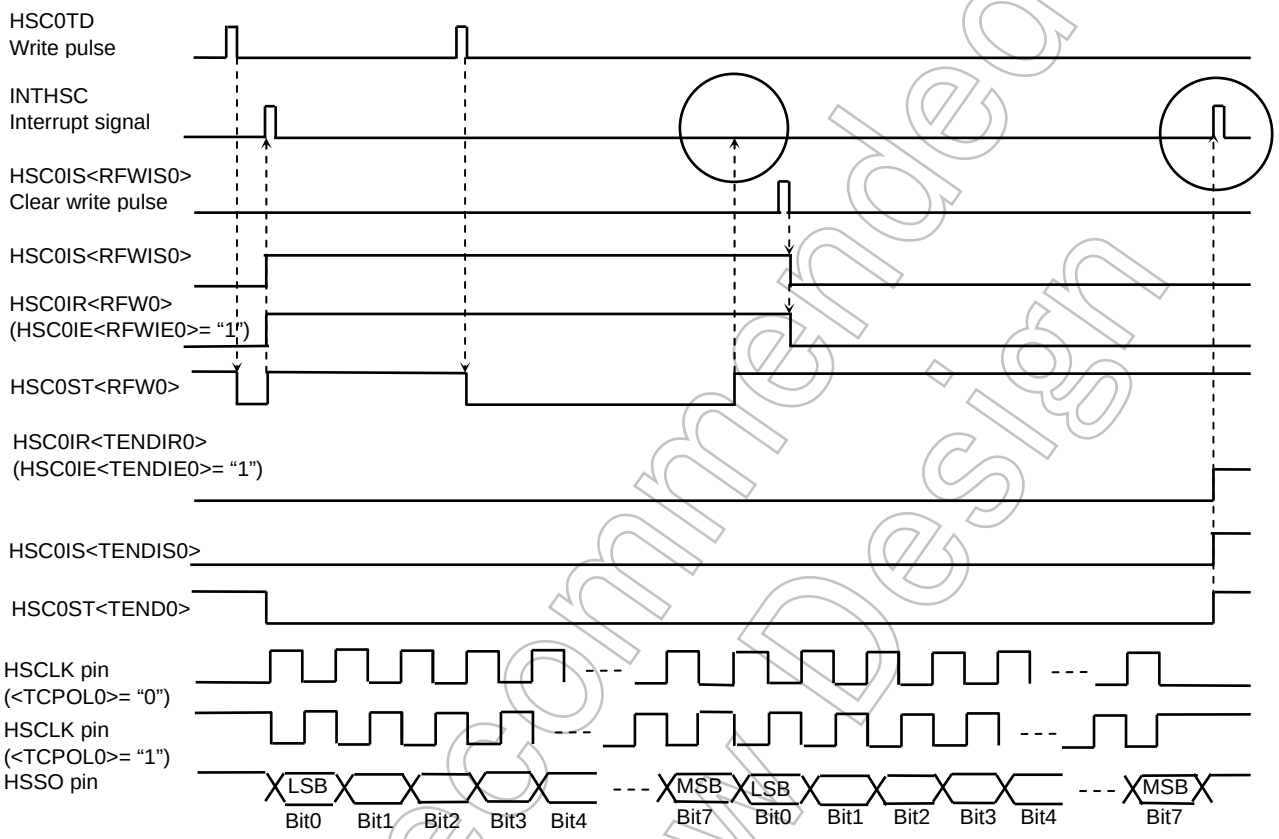

Figure 3.11.21 Transmission timing

In above condition, HSC0ST<RFW0> flag is set to "0" just after wrote transmission data. When data of HSC0TD register finish shifting to transmission register (HSC0TS), HSC0ST<RFW0> is set to "1", it is informed that can write next transmission data, start transmission clock and data from HSCLK pin and HSSO pin at same time with inform.

In this case, HSC0IS, HSC0IR change and INTHSC interrupt generate by synchronization to rising of HSC0ST<RFW0> flag. When HSC0IR register is setting to "1", interrupt is not generated even if HSC0ST<RFW0> was set to "1".

When finish transmission and lose data that must to transmit to HSC0TD register and HSC0TS register, transmission data and clock are stopped by setting "1" to HSC0ST<TEND0>, and INTHSC interrupt is generated at same time. In this case, if HSC0ST<TEND0> is set to "1" at different interrupt source, INTHSC is not generated. Therefore must to clear HSC0IS<RFW0> to "0".

- Setting condition 2:

  UNIT transmission in UNIT=8bit, LSB first

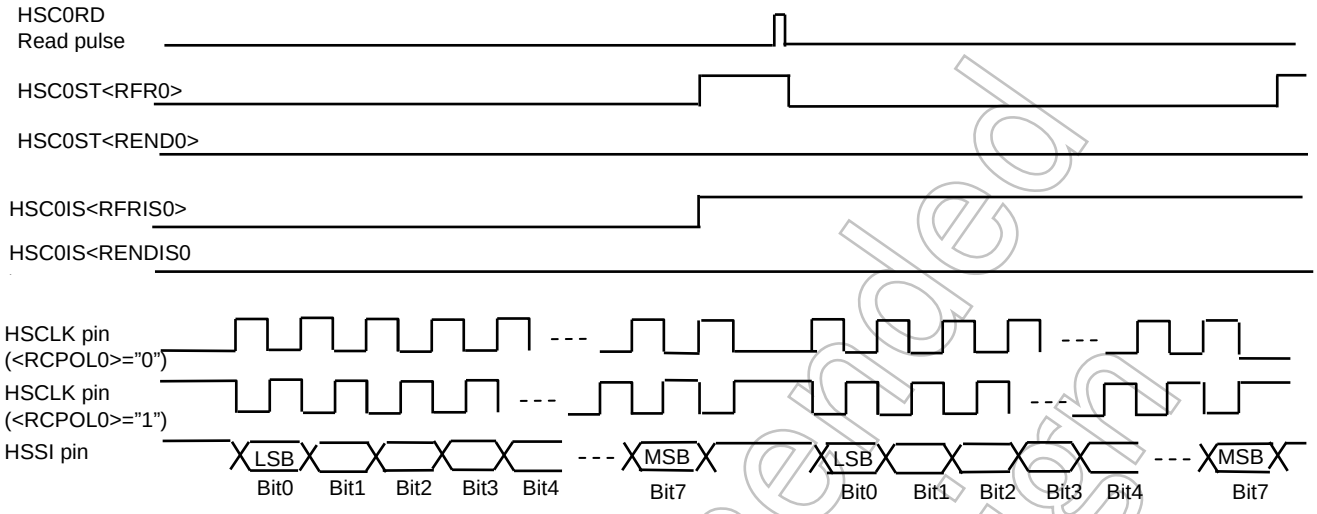

Figure 3.11.22 UNIT receiving (HSC0CT<RXUEN0>=1)

If set HSC0CT<RXUEN0> to "1" without valid receiving data to HSC0RD register (HSC0ST<RFR0>=0), UNIT receiving is started. When receiving is finished and stored receiving data to HSC0RD register, HSC0ST<RFR0> flag is set to "1", and inform that can read receiving data. Just after read HSC0RD register, HSC0ST<RFR0> flag is cleared to "0" and it start receiving next data automatically.

If be finished UNIT receiving, set HSC0CT<RXUEN0> to "0" after confirmed that HSC0ST<RFR0> was set to "1".

- Setting condition 3:

  Sequential receiving in UNIT=8 bit, LSB first

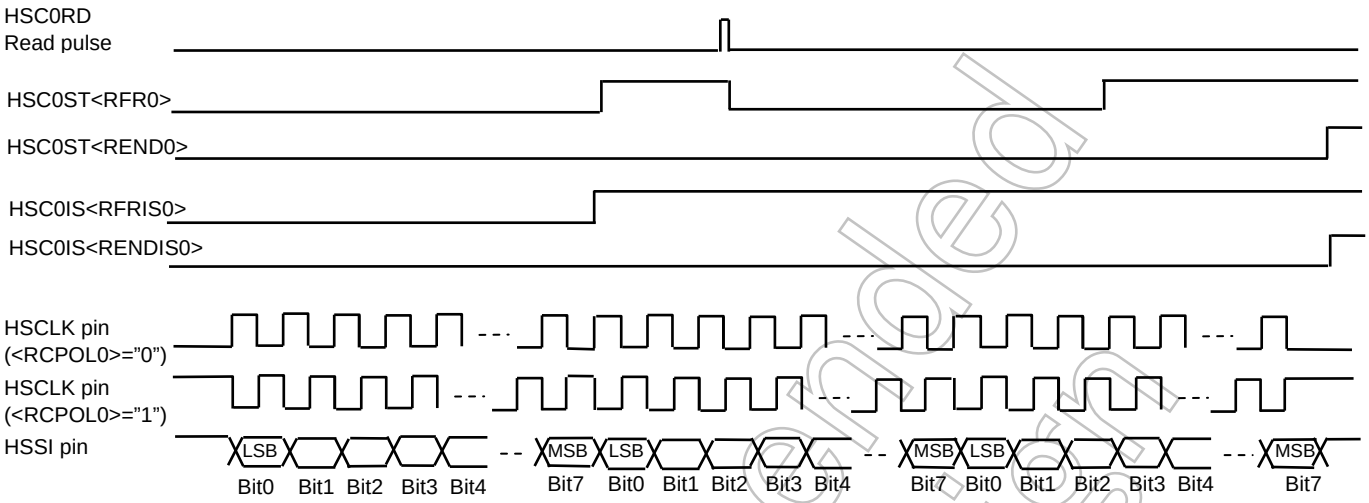

Figure 3.11.23 continuous receiving (HSC0CT<RXWEN0>=1)

If set HSC0CT<RXWEN0> to "1" without valid receiving data in HSC0RD register (HSC0ST<RFR0>=0), sequential receiving is started. When first receiving is finished and stored receiving data to HSC0RD register, HSC0ST<RFR0> flag is set to "1", and inform that can read receiving data. Sequential receiving is received until receiving data is stored to HSC0RD and HSC0RS registers If finished sequential receiving, set HSC0CT<RXWEN0> to "0" after confirmed that HSC0ST<REND0> was set to "1".

- Setting condition 4:

  Transmission by using micro DMA in UNIT=8bit, LSB first

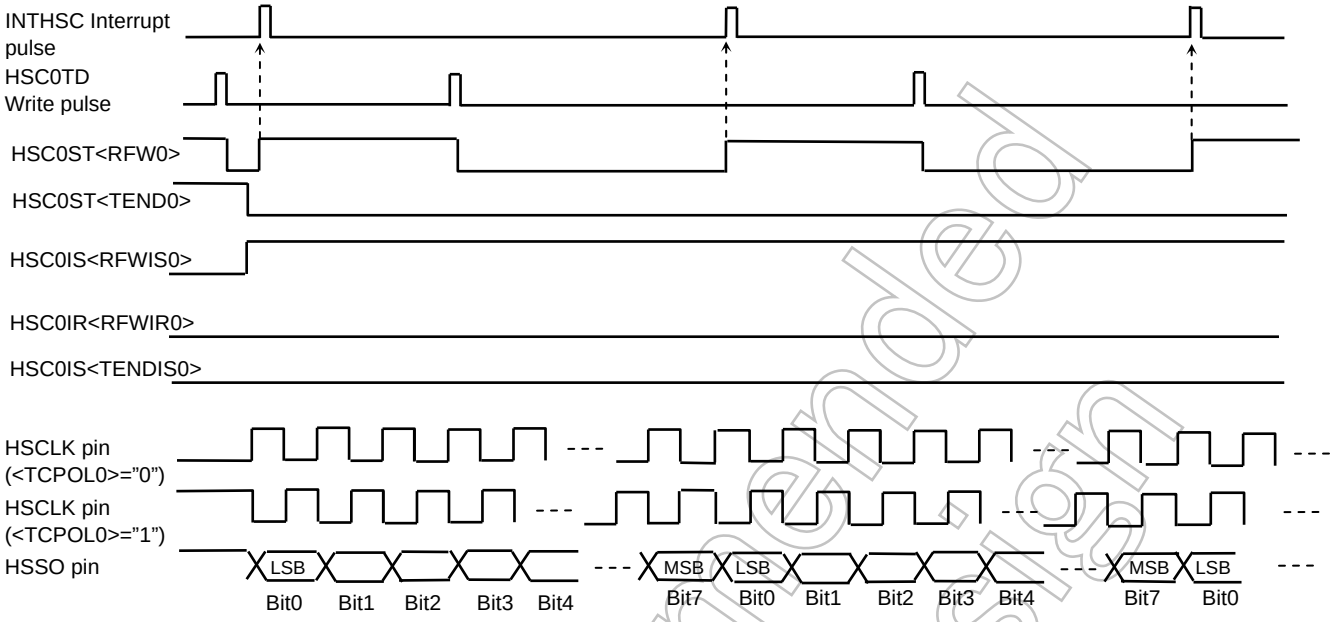

Figure 3.11.24 Micro DMA transmission (transmission)

If all bits of HSC0IE register are "0" and HSC0CT<DMAERFW0> is "1", transmission is started by writing transmission data to HSC0TD register.

If data of HSC0TD register is shifted to HSC0TS register and HSC0ST<RFW0> is set to "1" and can write next transmission data, INTHSC interrupt (RFW0 interrupt) is generated. By starting Micro DMA at this interrupt, can transmit sequential data automatically.

However, If transmit it at Micro DMA, set Micro DMA beforehand.

- Setting condition 5:

  Receiving by using micro DMA in UNIT=8bit, LSB first

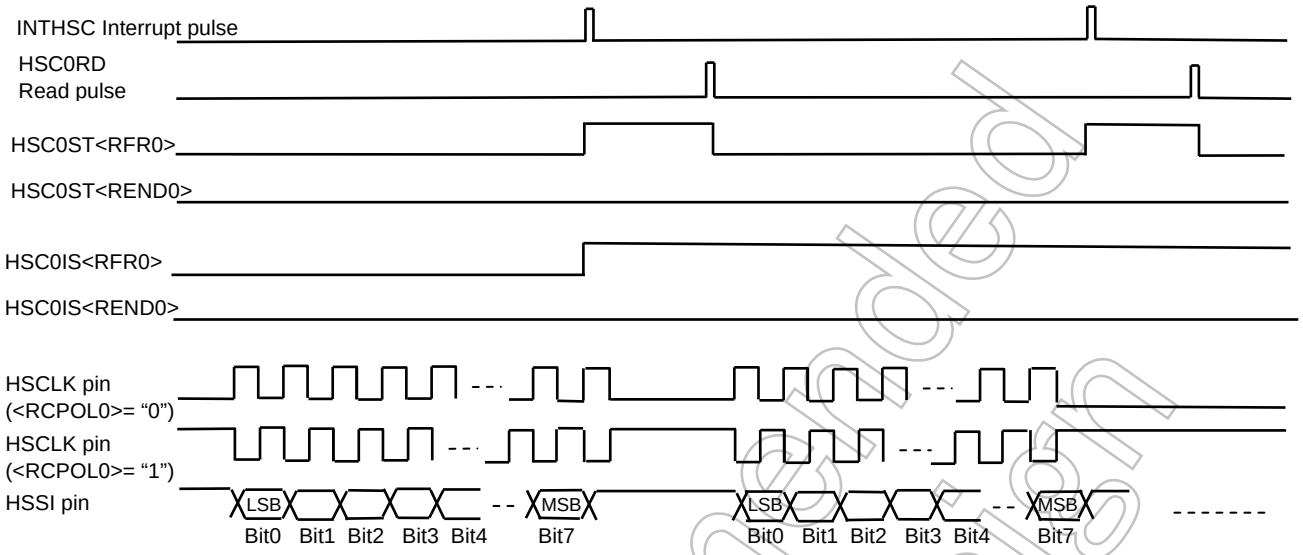

Figure 3.11.25 Micro DMA transmission (UNIT receiving (HSC0CT<RFUEN0>=1))

If all bits of HSC0IE register is "0" and HSC0CT<DMAERFR0> is "1", UNIT receiving is started by setting HSC0CT<RXUEN0> to "1". If receiving data is stored to HSC0RD register and can read receiving data, INTHSC interrupt (RFR0 interrupt) is generated. By starting Micro DMA at this interrupt, it can be received sequential data automatically.

However, If receive it at Micro DMA, set Micro DMA beforehand.

3.11.4 Example

Following is discription of HSC setting method.

(1) UNIT transmission

This example shows the case of transmission is executed by following setting, and it is generated INTHSC interrupt by finish transmission.

UNIT: 8bit
LSB first
Baud rate : $f_{SYS}/8$
Synchronous clock edge: Rising

Setting expample

```
    ld    (pffc), 0x38          ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (pfcr), 0x28          ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (hscsel), 0x01        ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

    ldw   (hsc0ct), 0x0040      ; Set data length to 8bit
    ldw   (hsc0md), 0x2c43      ; System clock enable, baud rate selection: fSYS/8
                                ; LSB first, synchronous clock edge setting: set to Rising

    ld    (hsc0ie), 0x08        ; Set to TEND0 interrupt enable
    ld    (intes1hsc), 0x10     ; Set INTHSC interrupt level to 1
    ei                          ; Interrupt enable (iff=0)

loop                            ; Confirm that transmission data register doesn't have no transmission data
    bit   1, (hsc0st)           ; <RFW0>=1 ?
    jr    z, loop

    ld    (hsc0td), 0x3a        ; Write Transmission data and Start transmission
    .
    .
    .
```

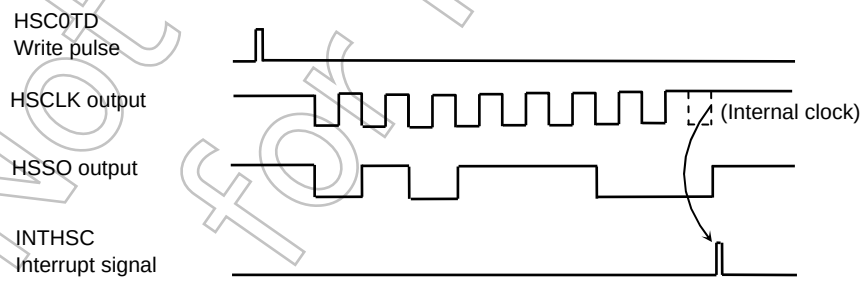

Figure 3.11.26 Example of UNIT transmission

(2) UNIT receiving

This example shows case of receiving is executed by following setting, and it is generated INTHSC interrupt by finish receiving.

UNIT: 8bit
LSB first
Baud rate selection : $f_{SYS}/8$
Synchronous clock edge: Rising

Setting example

```
ld    (pffc), 0x38          ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
ld    (pfcr), 0x28          ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
ld    (hscsel), 0x01        ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

ldw   (hsc0ct), 0x0040      ; Set data length to 8bit
ldw   (hsc0md), 0x2c43      ; System clock enable, baud rate selection: fSYS/8
                            ; LSB first, synchronous clock edge setting: set to Rising

ld    (hsc0ie), 0x01        ; Set to RFR0 interrupt enable
ld    (intes1hsc), 0x10     ; Set INTHSC interrupt level to 1
ei                          ; Interrupt enable (iff=0)

set   0x0, (hsc0ct)         ; Start UNIT receiving
.
.
.
```

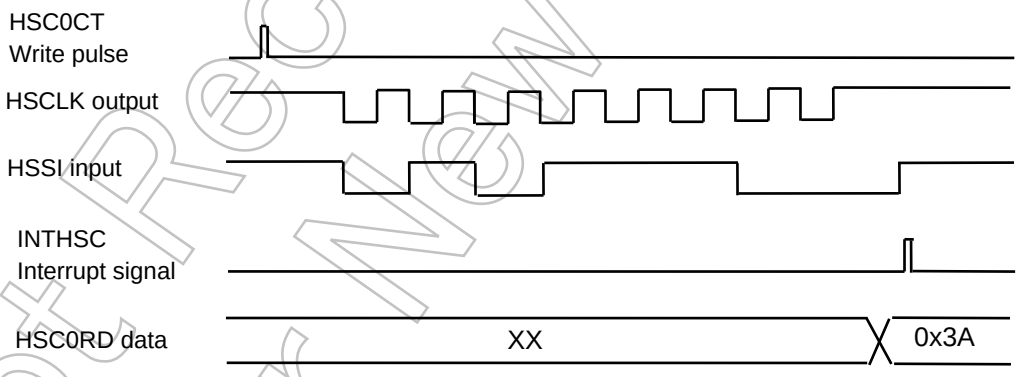

Figure 3.11.27 Example of UNIT receiving

(3) Sequential transmission

This example shows case of transmission is executed by following setting, and it is executed 2byte sequential transmission.

UNIT: 8bit
LSB first
Baud rate selection: $f_{SYS}/8$
Synchronous clock edge: Rising

Setting example

```
    ld    (pffc), 0x38          ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (pfcr), 0x28          ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (hscsel), 0x01        ; port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

    ldw   (hsc0ct), 0x0040      ; Set data length to 8bit
    ldw   (hsc0md), 0x2c43      ; System clock enable, baud rate selection: fsys/8
                                ; LSB first, synchronous clock edge setting: set to Rising

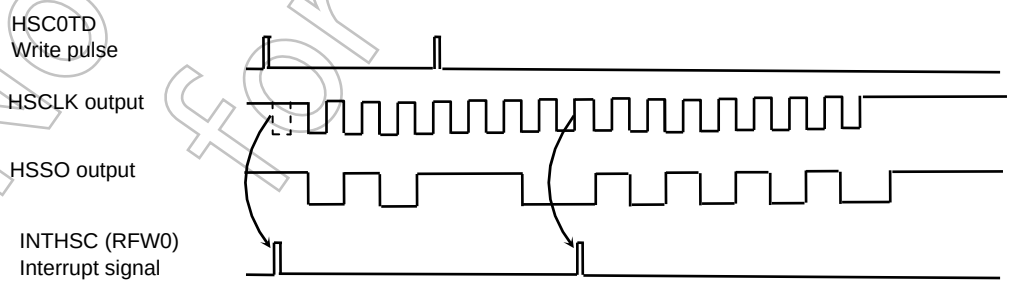
loop1:                  ; Confirm that transmission data register doesn't have no transmission data
    bit   1, (hsc0st)           ; <RFW0>=1 ?
    jr    z, loop1

    ld    (hsc0td), 0x3a        ; Write transmission data of first byte and start transmission

loop2                   ; Confirm that transmission data register doesn't have no-transmission data
    bit   1, (hsc0st)           ; <RFW0>=1 ?
    jr    z, loop2

    ld    (hsc0td), 0x55        ; Write transmission data of second byte

loop3:                  ; Confirm that transmission data register doesn't have no-transmission data
    bit   3, (hsc0st)           ; <TEND0>=1 ?
    jr    z, loop3
    .                           ; Finish transmission
    .
```



Note: Timing of this figure is an example. There is also that transmission interbal between first byte and sescond byte generate. (High baud rate etc.)

Figure 3.11.28 Example of sequential transmission

(4) Sequential receiving

This example shows case of receiving is executed by following setting, and it is executed 2byte sequential receiving.

UNIT: 8bit
LSB first
Baud rate selection: $f_{SYS}/8$
Synchronous clock edge: Rising

Setting example

```
    ld    (pffc), 0x38          ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (pfcr), 0x28          ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (hscsel), 0x01        ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

    ldw   (hsc0ct), 0x0040      ; Set data length to 8bit
    ldw   (hsc0md), 0x2c43      ; System clock enable, baud rate selection: fSYS/8
                                ; LSB first, synchronous clock edge setting: set to Rising
    set   0x01,(hsc0ct)         ; Start sequential receiving

loop1:                  ; Confirm that receiving data register has receiving data of first byte
    bit   0, (hsc0st)           ; <RFR0>=1 ?
    jr    z, loop1

loop2:                  ; Confirm that receiving data register has receiving data of second byte
    bit   2, (hsc0st)           ; <REND0>=1 ?
    jr    z, loop2

    res   0x01, (hsc0ct)        ; Sequential receiving disable

    ld    a, (hsc0rd)           ; Read receiving data of first byte

loop3:                  ; Confirm that receiving data of second byte is shifted from receiving data
                            shift register to receiving data register
    bit   0, (hsc0st)           ; <RFR0>=1 ?
    jr    z, loop3
    ld    w, (hsc0rd)           ; Read receiving data of second byte
```

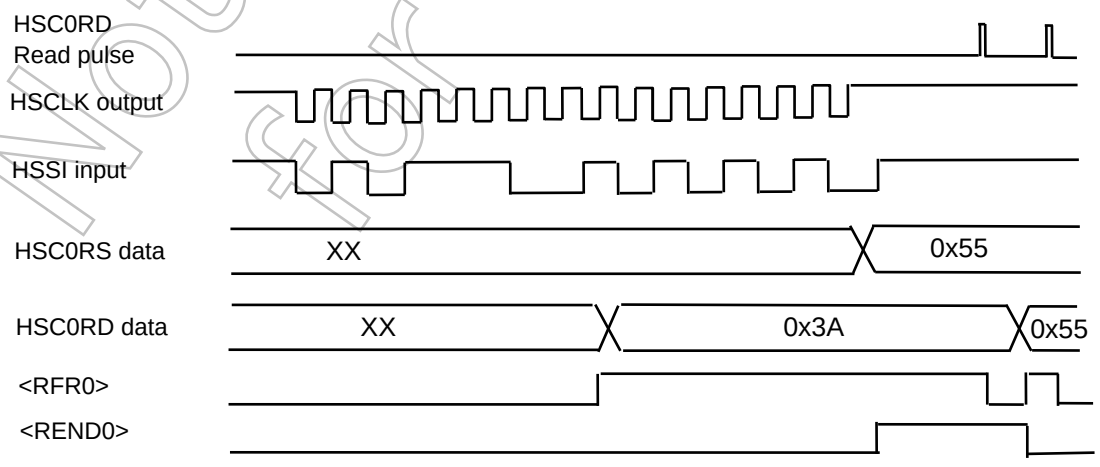


Figure 3.11.29 Example of sequential receiving

(5) Sequeintial Transmission by using micro DMA

This example shows case of sequential transmission of 4byte is executed at using micro DMA by following setting.

UNIT: 8bit
LSB first
Baud rate : $f_{SYS}/8$
Synchronous clock edge: Rising

Setting example

Main routine

```
;-- micro DMA setting --
    ld     (dma0v), 0x1D            ; Set micro DMA0 to INTHSC
    ld     wa, 0x0003               ; Set number of micro DMA transmission  to that number -1 (third time)
    ldc    dmac0, wa
    ld     a, 0x08                  ; micro DMA mode setting: source INC mode, 1 byte transfer
    ldc    dmam0, a

    ld     xwa, 0x806000            ; Set source address
    ldc    dmas0, xwa
    ld     xwa, 0xC10               ; Set source address to HSC0TD register
    ldc    dmad0, xwa

;-- HSC setting --
    ld     (pffc), 0x38             ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld     (pfcr), 0x28             ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld     (hscsel), 0x01           ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

    ldw    (hsc0ct), 0x0040         ; Set data length to 8bit
    ldw    (hsc0md), 0x2c43         ; System clock enable, baud rate selection: fSYS/8
                                    ; LSB first, synchronous clock edge setting: set to Rising

    ld     (hsc0ie), 0x00           ; Set to interrupt disable
    set    1, (hsc0ct+1)            ; Set micro DMA operation by RFW0 to enable
    ld     (intetc01), 0x01         ; Set INTTC0 interrupt level to 1
    ei                              ; Interrupt enable (iff=0)

loop1:                      ; Confirm that transmission data register doesn't have no transmission data
    bit    1, (hsc0st)              ; <RFW0>=1 ?
    jr     z, loop1

    ld     (hsc0td), 0x3a           ; Write Transmission data and Start transmission
```

Interrupt routine (INTTC0)

```
loop2:
    bit    1, (hsc0st)              ; <RFW0> = 1 ?
    jr     z, loop2
    bit    3, (hsc0st)              ; <TEND0> = 1 ?
    jr     z, loop2
    nop
```

(6) UNIT receiving by using micro DMA

This example shows case of UNIT receiving sequentially 4byte is executed at using micro DMA by following setting.

UNIT: 8bit
LSB first
Baud rate : $f_{SYS}/8$
Synchronous clock edge: Rising

Setting example

Main routine

```
;-- micro DMA setting --
    ld    (dma0v), 0x1D          ; Set micro DMA0 to INTHSC
    ld    wa, 0x0003             ; Set number of micro DMA transmission to that number -1 (third time)
    ldc   dmac0, wa
    ld    a, 0x00                ; micro DMA mode setting: source INC mode, 1 byte transfer
    ldc   dmam0, a

    ld    xwa, 0xC12             ; Set source address to HSC0RD register
    ldc   dmas0, xwa
    ld    xwa, 0x807000          ; Set source address
    ldc   dmad0, xwa

;-- HSC setting --
    ld    (pffc), 0x38           ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (pfcr), 0x28           ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK
    ld    (hscsel), 0x01         ; Port setting PF3: HSSO, PF4: HSSI, PF5: HSCLK

    ldw   (hsc0ct), 0x0040       ; Set data length to 8bit
    ldw   (hsc0md), 0x2c43       ; System clock enable, baud rate selection: fSYS/8
                                 ; LSB first, synchronous clock edge setting: set to Rising

    ld    (hsc0ie), 0x00         ; Set to interrupt disable
    set   0, (hsc0ct+1)          ; Set micro DMA operation by RFR0 to enable
    ld    (intetc01), 0x01       ; Set INTTC0 interrupt level to 1
    ei                           ; Interrupt enable (iff=0)

    set   0x0, (hsc0ct)          ; Start UNIT receiving
```

Interrupt routine (INTTC0)

```
loop2:                           ; Wait receiving finish case of UNIT receiving
    bit   0, (hsc0st)            ; <RFR0> = 1 ?
    jr    z, loop2
    res   0, (hsc0ct)            ; UNIT receiving disable
    ld    a, (hsc0rd)            ; Read last receiving data
    Nop
```

3.12 Analog/Digital Converter

The TMP92CY23/CD23A incorporates a 10-bit successive approximation type analog/digital converter (AD converter) with 12-channel analog input.

Figure 3.12.1 is a block diagram of the AD converter. The 12-channel analog input pins (AN0 to AN11) are shared with the input only port (Port G and Port L) so they can be used as an input port.

Note: When IDLE2, IDLE1 or STOP mode is selected, in order to reduce the power consumption, the system may enter a stand-by mode with some timings even though the internal comparator is still enabled. Therefore be sure to check that AD converter operations are halted before a HALT instruction is executed.

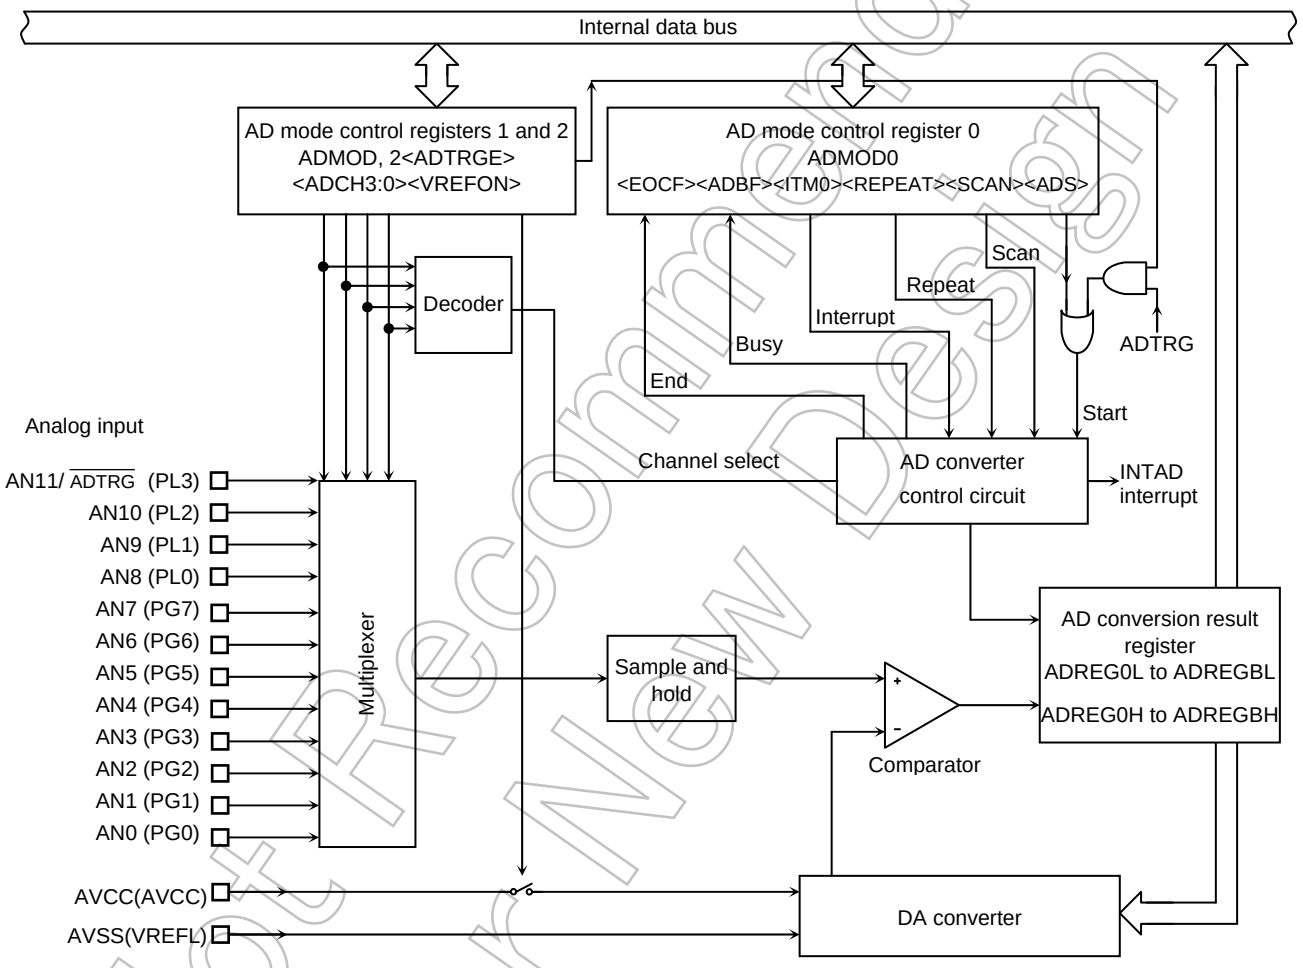

Figure 3.12.1 Block Diagram of AD Converter

3.12.1 Analog/Digital Converter Registers

The AD converter is controlled by the three AD mode control registers: ADMOD0, ADMOD1 and ADMOD2. The 24 AD conversion data result registers (ADREG0H/L to ADREGBH/L) store the results of AD conversion.

Figure 3.12.2 to Figure 3.12.10 show the registers related to the AD converter.

AD Mode Control Register 0

ADMOD0 (12B8H)	7	6	5	4	3	2	1	0
Bit symbol	EOCF	ADBF	–	–	ITM0	REPEAT	SCAN	ADS

Figure 3.12.10 Register for AD Converter

3.12.2 Description of Operation

(1) Analog reference voltage

A high level analog reference voltage is applied to the AVCC pin; a low level analog reference voltage is applied to the AVSS pin. To perform AD conversion, the reference voltage, the difference between AVCC and AVSS, is divided by 1024 using string resistance. The result of the division is then compared with the analog input voltage.

To turn off the switch between AVCC and AVSS, write "0" to ADMOD1 <VREFON> in AD mode control register 1. To start AD conversion in the OFF state, first write "1" to ADMOD1<VREFON>, wait 3 μs until the internal reference voltage stabilizes (this is not related to fc), then set ADMOD0<ADS> to "1".

(2) Analog input channel selection

The analog input channel selection varies depending on the operation mode of the AD converter.

- In analog input channel fixed mode (ADMOD0<SCAN> = "0")
  Setting ADMOD1<ADCH1:0> selects one of the input pins AN0 to AN3 as the input channel.
- In analog input channel scan mode (ADMOD0<SCAN> = "1")
  Setting ADMOD1<ADCH1:0> selects one of the four scan modes.

Table 3.12.1 illustrates analog input channel selection in each operation mode.

On a reset, ADMOD0<SCAN> is set to 0 and ADMOD1<ADCH3:0> is initialized to "00". Thus pin AN0 is selected as the fixed input channel. Pins not used as analog input channels can be used as standard input port pins.

Table 3.12.1 Analog Input Channel Selection

<ADCH3:0>	Channel Fixed <SCAN> = "0"	Channel Scan <SCAN> = "1"
0000	AN0	AN0
0001	AN1	AN0 → AN1
0010	AN2	AN0 → AN1 → AN2
0011	AN3	AN0 → AN1 → AN2 → AN3
0100	AN4	AN0 → AN1 → AN2 → AN3 → AN4
0101	AN5	AN0 → AN1 → AN2 → AN3 → AN4 → AN5
0110	AN6	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6
0111	AN7	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7
1000	AN8	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8
1001	AN9	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8→ AN9
1010	AN10	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8→ AN9→ AN10
1011	AN11	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8→ AN9→ AN10→ AN11

(3) Starting AD conversion

To start AD conversion, write "1" to ADMOD0<ADS> in AD mode control register "0" or ADMOD2<ADTRGE> in AD mode control register 2, and input falling edge on $\overline{\text{ADTRG}}$ pin. When AD conversion starts, the AD conversion busy flag ADMOD0<ADBF> will be set to "1", indicating that AD conversion is in progress.

During AD conversion, a falling edge input on the $\overline{\text{ADTRG}}$ pin will be ignored.

(4) AD conversion modes and the AD conversion end interrupt

The four AD conversion modes are:

- Channel fixed single conversion mode
- Channel scan single conversion mode
- Channel fixed repeat conversion mode
- Channel scan repeat conversion mode

The ADMOD0<REPEAT> and ADMOD0<SCAN> settings in AD mode control register 0 determine the AD mode setting.

Completion of AD conversion triggers an INTAD AD conversion end interrupt request. Also, ADMOD0<EOCF> will be set to "1" to indicate that AD conversion has been completed.

1. Channel fixed single conversion mode

   Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to "00" selects conversion channel fixed single conversion mode.

   In this mode, data on one specified channel is converted once only. When the conversion has been completed, the ADMOD0<EOCF> flag is set to "1", ADMOD0<ADBF> is cleared to "0", and an INTAD interrupt request is generated.

2. Channel scan single conversion mode

   Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to "01" selects conversion channel scan single conversion mode.

   In this mode, data on the specified scan channels is converted once only. When scan conversion has been completed, ADMOD0<EOCF> is set to "1", ADMOD0<ADBF> is cleared to "0", and an INTAD interrupt request is generated.

3. Channel fixed repeat conversion mode

   Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to "10" selects conversion channel fixed repeat conversion mode.

   In this mode, data on one specified channel is converted repeatedly. When conversion has been completed, ADMOD0<EOCF> is set to "1" and ADMOD0<ADBF> is not cleared to "0" but held at "1". INTAD interrupt request generation timing is determined by the setting of ADMOD0<ITM0>.

   Clearing <ITM0> to "0" generates an interrupt request every time an AD conversion is completed.

   Setting <ITM0> to "1" generates an interrupt request on completion of every fourth conversion.

4. Channel scan repeat conversion mode

   Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to "11" selects conversion channel scan repeat conversion mode.

   In this mode, data on the specified scan channels is converted repeatedly. When each scan conversion has been completed, ADMOD0<EOCF> is set to "1" and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to "0" but held at "1".

   To stop conversion in a repeat conversion mode (e.g., in cases 3. and 4.), write "0" to ADMOD0<REPEAT>. After the current conversion has been completed, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to "0".

   Switching to a halt state (IDLE2 mode with ADMOD1<I2AD> cleared to "0", IDLE1 mode or STOP mode) immediately stops operation of the AD converter even when AD conversion is still in progress. In repeat conversion modes (e.g., in cases 3. and 4.), when the halt is released, conversion restarts from the beginning. In single conversion modes (e.g., in cases 1. and 2.), conversion does not restart when the halt is released (the converter remains stopped).

   Table 3.12.2 shows the relationship between the AD conversion modes and interrupt requests.

Table 3.12.2 Relationship between AD Conversion Modes and Interrupt Requests

Mode	Interrupt Request Generation	ADMOD0		
		<ITM0>	<REPEAT>	<SCAN>
Channel fixed single conversion mode	After completion of conversion	X	0	0
Channel scan single conversion mode	After completion of scan conversion	X	0	1
Channel fixed repeat conversion mode	Every conversion	0	1	0
	Every fourth conversion	1		
Channel scan repeat conversion mode	After completion of every scan conversion	X	1	1

X: Don't care

(5) AD conversion time

84 states (4.2μs at f_{SYS} = 20 MHz) are required for the AD conversion of one channel.

(6) Storing and reading the results of AD conversion

The AD conversion data upper and lower registers (ADREG0H/L to ADREGBH/L) store the results of AD conversion. (ADREG0H/L to ADREGBH/L are read-only registers.)

In channel fixed repeat conversion mode, the conversion results are stored successively in registers from ADREG0H/L to ADREGBH/L. In other modes from AN0 to AN11 conversion results are stored in from ADREG0H/L to ADREGBH/L respectively.

Table 3.12.3 shows the correspondence between the analog input channels and the registers which are used to hold the results of AD conversion.

Table 3.12.3 Correspondence between Analog Input Channels and AD Conversion Result Registers

Analog Input Channel (Port G/Port L)	AD Conversion Result Register	
	Conversion Modes Other than at Right	Channel Fixed Repeat Conversion Mode (ADMOD0<ITM0> = "1")
AN0	ADREG0H/L	
AN1	ADREG1H/L	
AN2	ADREG2H/L	
AN3	ADREG3H/L	ADREG0H/L ←
AN4	ADREG4H/L	↓
AN5	ADREG5H/L	ADREG1H/L
AN6	ADREG6H/L	↓
AN7	ADREG7H/L	ADREG2H/L
AN8	ADREG8H/L	↓
AN9	ADREG9H/L	ADREG3H/L ←
AN10	ADREGAH/L	
AN11	ADREGBH/L	

The AD conversion data storage flag <ADRxRF> indicates whether the AD conversion result register has been read or not. When a conversion result is stored in the AD conversion result register, the flag is set to "1". When either of the AD conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to "0".

Reading the AD conversion result also clears the AD conversion end flag ADMOD0<EOCF> to "0".

Setting example:

1. Convert the analog input voltage on the AN3 pin and write the result to memory address 2800H using the AD interrupt (INTAD) processing routine.

Main routine:

		7	6	5	4	3	2	1	0	
INTEPAD	←	X	−	−	−	X	1	0	0	Enable INTAD and set it to interrupt level 4.
ADMOD1	←	1	1	0	0	0	0	1	1	Set pin AN3 to be the analog input channel.
ADMOD0	←	X	X	0	0	0	0	0	1	Start conversion in channel fixed single conversion mode.

Interrupt routine processing example:

WA	←	ADREG3H/L	Read value of ADREG3L and ADREG3H into 16-bits general-purpose register WA.
WA	←	> > 6	Shift contents read into WA six times to right and ”0” fill upper bits.
(2800H)	←	WA	Write contents of WA to memory address 2800H.

2. This example repeatedly converts the analog input voltages on the three pins AN0, AN1 and AN2, using channel scan repeat conversion mode.

		7	6	5	4	3	2	1	0	
INTEPAD	←	X	−	−	−	X	0	0	0	Disable INTAD.
ADMOD1	←	1	1	0	0	0	0	1	0	Set pins AN0 to AN2 to be the analog input channels.
ADMOD0	←	X	X	0	0	0	1	1	1	Start conversion in channel scan repeat conversion mode.

X: Don't care, −: No change

3.13 Watchdog Timer (Runaway detection timer)

The TMP92CY23/CD23A contains a watchdog timer of runaway detecting.

The watchdog timer (WDT) is used to return the CPU to the normal state when it detects that the CPU has started to malfunction (runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction.

Connecting the watchdog timer output to the reset pin internally forces a reset.

(The level of external $\overline{\text{RESET}}$ pin is not changed.)

3.13.1 Configuration

Figure 3.13.1 is a block diagram of the watchdog timer (WDT).

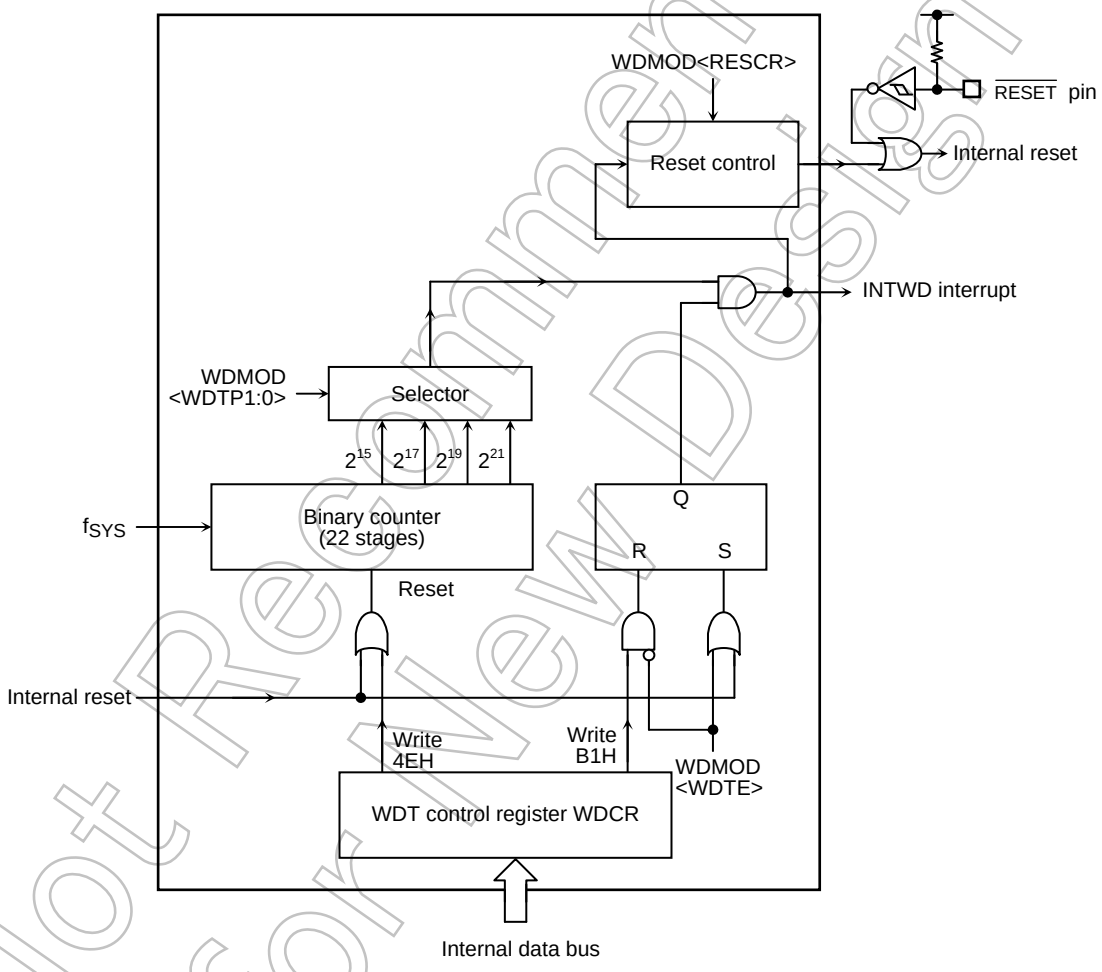

Figure 3.13.1 Block Diagram of Watchdog Timer

Note: Care must be exercised in the overall design of the apparatus since the watchdog timer may fail to function correctly due to external noise, etc.

3.13.2 Operation

The watchdog timer generates an INTWD interrupt when the detection time set in the WDMOD<WDTP1:0> has elapsed. The watchdog timer must be cleared "0" in software before an INTWD interrupt will be generated. If the CPU malfunctions (e.g., if runaway occurs) due to causes such as noise, but does not execute the instruction used to clear the binary counter, the binary counter will overflow and an INTWD interrupt will be generated. The CPU will detect malfunction (runaway) due to the INTWD interrupt and in this case it is possible to return to the CPU to normal operation by means of an anti-malfunction program.

The watchdog timer begins operating immediately on release of the watchdog timer reset.

The watchdog timer is halted in IDLE1 or STOP mode.

When the device is in IDLE2 mode, the operation of WDT depends on the WDMOD<I2WDT> setting. Ensure that WDMOD<I2WDT> is set before the device enters IDLE2 mode.

The watchdog timer consists of a 22-stage binary counter which uses the clock f_{SYS} as the input clock. The binary counter can output $2^{15}/f_{SYS}$, $2^{17}/f_{SYS}$, $2^{19}/f_{SYS}$ and $2^{21}/f_{SYS}$.

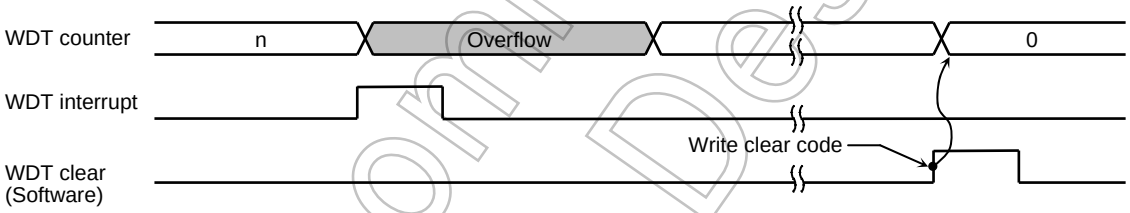

Figure 3.13.2 Normal Mode

The runaway detection result can also be connected to the reset pin internally.

In this case, the reset time will be between 22 and 29 system clocks (70.4 to 92.8 μs at f_{OSCH} = 10 MHz) as shown in Figure 3.13.3. After a reset, the f_{SYS} clock is $f_{FPH}/2$, where f_{FPH} is generated by dividing the high-speed oscillator clock (f_{OSCH}) by sixteen through the clock gear function

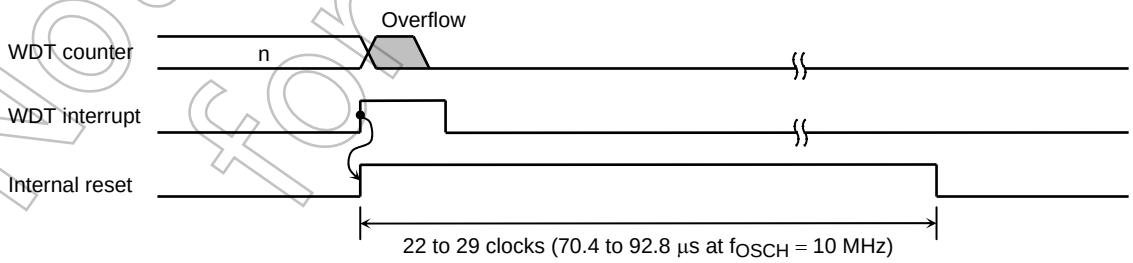

Figure 3.13.3 Reset Mode

3.13.3 Control Registers

The watchdog timer (WDT) is controlled by two control registers WDMOD and WDCR.

(1) Watchdog timer mode register (WDMOD)

1. Setting the detection time for the watchdog timer in <WDTP1:0>

   This 2-bit register is used for setting the watchdog timer interrupt time used when detecting runaway.

   On a reset this register is initialized to WDMOD<WDTP1:0> = "00".

   The detection time for WDT is $2^{15}/f_{SYS}$ [s].

2. Watchdog timer enable/disable control register <WDTE>

   At reset, the WDMOD<WDTE> is initialized to "1", enabling the watchdog timer.

   To disable the watchdog timer, it is necessary to set this bit to "0" and to write the disable code (B1H) to the watchdog timer control register (WDCR). This makes it difficult for the watchdog timer to be disabled by runaway.

   However, it is possible to return the watchdog timer from the disabled state to the enabled state merely by setting <WDTE> to "1".

3. Watchdog timer out reset connection <RESCR>

   This register is used to connect the output of the watchdog timer with the RESET terminal internally. Since WDMOD<RESCR> is initialized to "0" at reset, a reset by the watchdog timer will not be performed.

(2) Watchdog timer control register (WDCR)

This register is used to disable and clear the binary counter for the watchdog timer.

- Disable control

  The watchdog timer can be disabled by clearing WDMOD<WDTE> to "0" and then writing the disable code (B1H) to the WDCR register.

WDCR	←	0	1	0	0	1	1	1	0	Write the clear code (4EH).
WDMOD	←	0	–	–	X	0	–	–	0	Clear WDMOD <WDTE> to "0".
WDCR	←	1	0	1	1	0	0	0	1	Write the disable code (B1H).

- Enable control

  Set WDMOD<WDTE> to "1".

- Watchdog timer clear control

  To clear the binary counter and cause counting to resume, write the clear code (4EH) to the WDCR register.

WDCR	←	0	1	0	0	1	1	1	0	Write the clear code (4EH).

Note1: If the disable control is used, set the disable code (B1H) to WDCR after writing the clear code (4EH) once. (Please refer to setting example.)

Note2: If the watchdog timer setting is changed, change setting after setting to disable condition once.

3.14 Special timer for CLOCK

The TMP92CY23/CD23A includes a timer which is used for a clock operation.

An interrupt (INTRTC) can be generated each 0.0625[s] or 0.125[s] or 0.25[s] or 0.50[s] by using a low-frequency clock of 32.768 kHz. A clock function can be easily used.

Special timer for Clock can operate in all modes in which a low-frequency oscillation is operated. In addition, INTRTC can return from each standby mode except STOP mode.

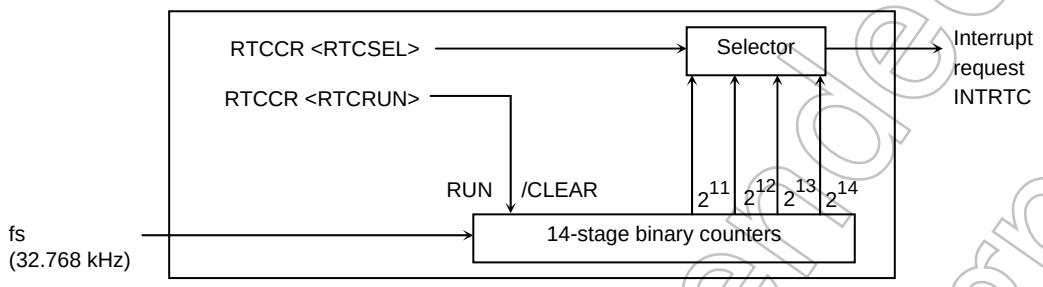

Figure 3.14.1 Block Diagram for Special timer for CLOCK

The Special timer for CLOCK is controlled by Special timer for CLOCK control register (RTCCR).

Figure 3.14.2 shows the timer for real time clock control register.

RTCCR (1310H)

	7	6	5	4	3	2	1	0

3.15 Program patch logic

The TMP92CY23/CD23A has a program patch logic, which enables the user to fix the program code in the Internal ROM. Patch program must be read into Internal RAM from external memory during the startup routine.

Up to eight 4-byte sequences or banks (32-bytes in total) can be replaced with patch code. More significant code correction can be performed by replacing program code with 1-byte instruction code which generates a software interrupt (SWI) to make a branch to a specified location in the Internal RAM area.

The program patch logic only compares addresses in the Internal ROM area; it cannot fix the program code in the Internal peripheral, Internal RAM and external ROM areas.

Each of eight banks is independently programmable, and functionally equivalent. In the following sections, any references to bank0 also apply to other banks.

3.15.1 Block Diagram

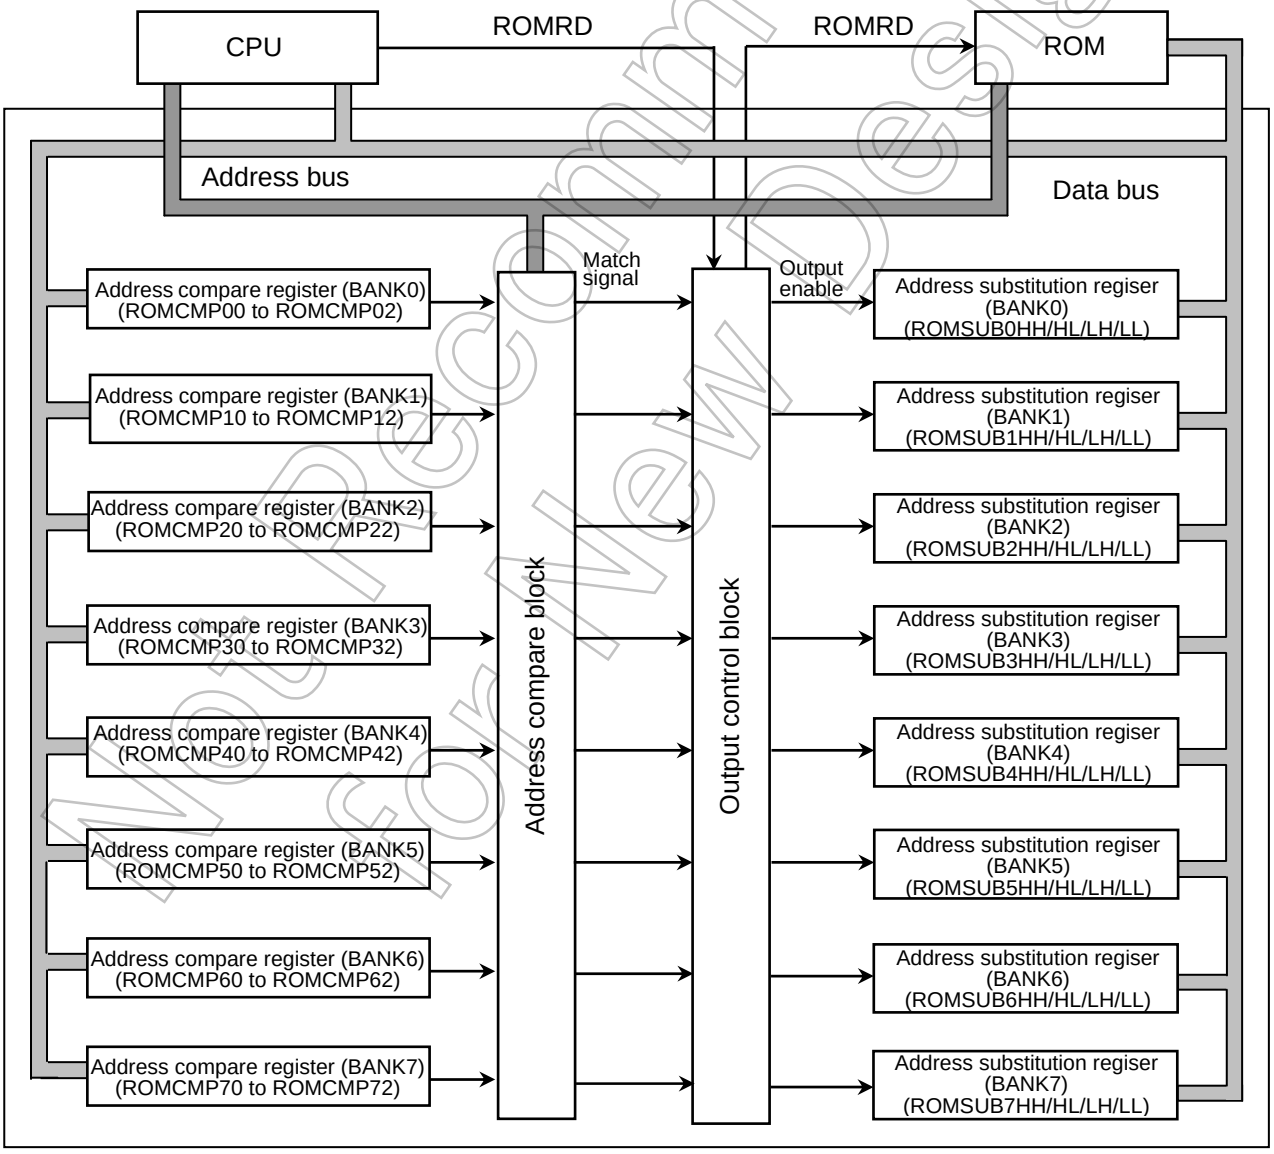

Figure 3.15.1 Program Patch Logic Diagram

Note: Don't set the same value to an address compare register (Bank0 to 7).

3.15.2 SFR Descriptions

The program patch logic consists of eight banks (0 to 7). Each bank is provided with 3-bytes of address compare registers (ROMCMP00 to ROMCMP72) and 4-bytes of address substitution registers (ROMSUBLL, ROMSUBLH, ROMSUBHL and ROMSUBHH).

BANK0 Address Compare Register 0

ROMCMP00 (1400H)

	7	6	5	4	3	2	1	0
Bit symbol	ROMC07	ROMC06	ROMC05	ROMC04	ROMC03	ROMC02

Figure 3.15.17 Address Substitution Registers (Banks 7)

3.15.3 Operation

(1) Replacing data

Correction procedure:

Load the address compare registers ROMCMPx0 to ROMCMPx2 (banks No. x = 0 to 7) with the target address where ROM data need be replaced. Store 4-byte patch code in the ROMSUBxLL, ROMSUBxLH, ROMSUBxHL and ROMSUBxHH (banks No. x = 0 to 7) registers.

After each register store , when the CPU address matches the value stored in the ROMCMPx0 to ROMCMPx2 (banks No. x = 0 to 7) registers, the program patch logic disables RD output to the internal ROM and drives out the code stored in the ROMSUBxLL to ROMSUBxHH (banks No. x = 0 to 7) to the internal bus. The CPU thus fetches the patch code.

The following shows some examples:

Examples:

a. Replacing 00H at address FF1230H with AAH

		7	6	5	4	3	2	1	0	
ROMCMP00	←	0	0	1	1	0	0	0	0	Stores 30H in address compare register 0 for bank0.
ROMCMP01	←	0	0	0	1	0	0	1	0	Stores 12H in address compare register 1 for bank0.
ROMCMP02	←	1	1	1	1	1	1	1	1	Stores FFH in address compare register 2 for bank0.
ROMSUB0LL	←	1	0	1	0	1	0	1	0	Store AAH in address substitution register LL for bank0.
ROMSUB0LH	←	0	0	0	1	0	0	0	1	Store 11H in address substitution register LH for bank0.
ROMSUB0HL	←	0	0	1	0	0	0	1	0	Store 22H in address substitution register HL for bank0.
ROMSUB0HH	←	0	0	1	1	0	0	1	1	Store 33H in address substitution register HH for bank0.

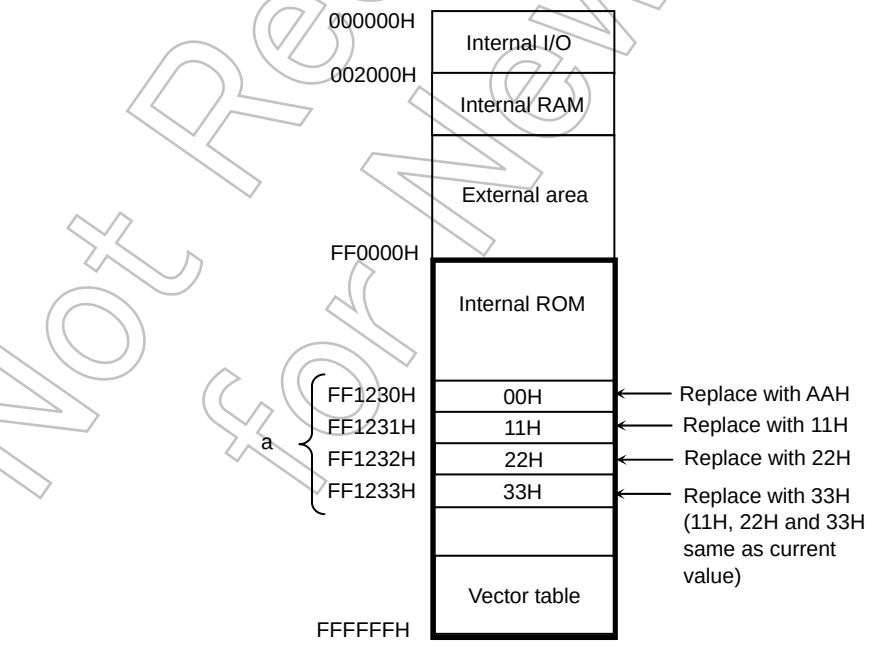

Figure 3.15.18 Example Patch Code Implementation

b. Replacing 33H at address FF1233H with BBH

		7	6	5	4	3	2	1	0	
ROMCMP00	←	0	0	1	1	0	0	0	0	Stores 30H in address compare register 0 for bank0.
ROMCMP01	←	0	0	0	1	0	0	1	0	Stores 12H in address compare register 1 for bank0.
ROMCMP02	←	1	1	1	1	1	1	1	1	Stores FFH in address compare register 2 for bank0.
ROMSUB0LL	←	0	0	0	0	0	0	0	0	Store 00H in address substitution register LL for bank0
ROMSUB0LH	←	0	0	0	1	0	0	0	1	Store 11H in address substitution register LH for bank0
ROMSUB0HL	←	0	0	1	0	0	0	1	0	Store 22H in address substitution register HL for bank0.
ROMSUB0HH	←	1	0	1	1	1	0	1	1	Store BBH in address substitution register HH for bank0.

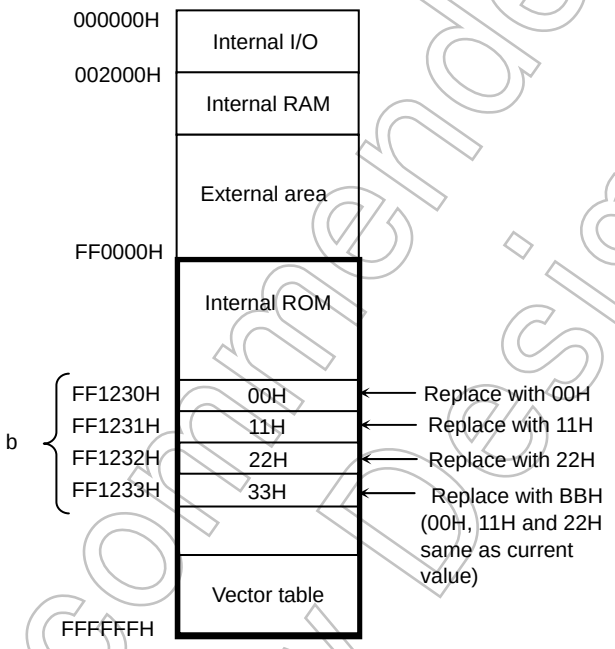

Figure 3.15.19 Example Patch Code Implementation

c. Replacing 00H at address FF1230H with AAH, 11H at address FF1231H with BBH, 22H at address FF1232H with CCH and 33H at address FF1233H with DDH

		7	6	5	4	3	2	1	0	
ROMCMP00	←	0	0	1	1	0	0	0	0	Stores 30H in address compare register 0 for bank0.
ROMCMP01	←	0	0	0	1	0	0	1	0	Stores 12H in address compare register 1 for bank0.
ROMCMP02	←	1	1	1	1	1	1	1	1	Stores FFH in address compare register 2 for bank0.
ROMSUB0LL	←	1	0	1	0	1	0	1	0	Store AAH in address substitution register LL for bank0
ROMSUB0LH	←	1	0	1	1	1	0	1	1	Store BBH in address substitution register LH for bank0.
ROMSUB0HL	←	1	1	0	0	1	1	0	0	Store CCH in address substitution register HL for bank0.
ROMSUB0HH	←	1	1	0	1	1	1	0	1	Store DDH in address substitution register HH for bank0.

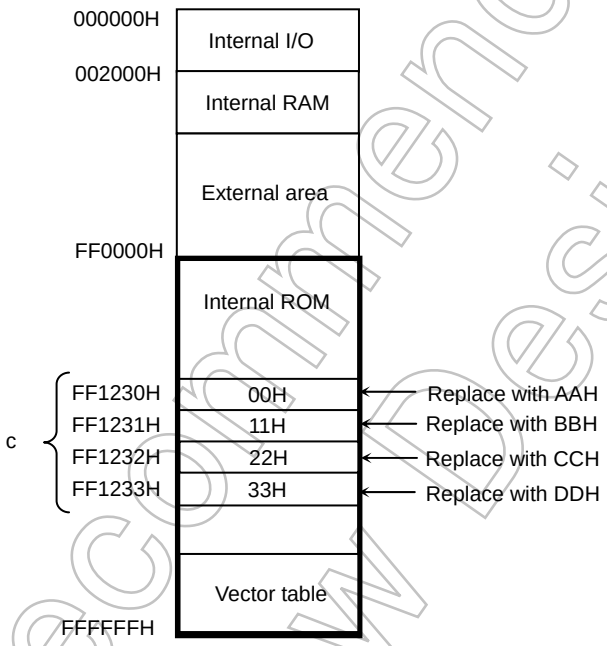

Figure 3.15.20 Example Patch Code Implementation

d. Replacing 11H at address FF1231H with AAH, 22H at address FF1232H with BBH, 33H at address FF1233H with CCH and 44H at address FF1234H with DDH (Requiring two banks)

		7	6	5	4	3	2	1	0	
ROMCMP00	←	0	0	1	1	0	0	0	0	Stores 30H in address compare register 0 for bank0.
ROMCMP01	←	0	0	0	1	0	0	1	0	Stores 12H in address compare register 1 for bank0.
ROMCMP02	←	1	1	1	1	1	1	1	1	Stores FFH in address compare register 2 for bank0.
ROMSUB0LL	←	0	0	0	0	0	0	0	0	Store 00H in address substitution register LL for bank0
ROMSUB0LH	←	1	0	1	0	1	0	1	0	Store AAH in address substitution register LH for bank0.
ROMSUB0HL	←	1	0	1	1	1	0	1	1	Store BBH in address substitution register HL for bank0
ROMSUB0HH	←	1	1	0	0	1	1	0	0	Store CCH in address substitution register HH for bank0
ROMCMP10	←	0	0	1	1	0	1	0	0	Stores 34H in address compare register 0 for bank1.
ROMCMP11	←	0	0	0	1	0	0	1	0	Stores 12H in address compare register 1 for bank1.
ROMCMP12	←	1	1	1	1	1	1	1	1	Stores FFH in address compare register 2 for bank1.
ROMSUB1LL	←	1	1	0	1	1	1	0	1	Store DDH in address substitution register LL for bank1
ROMSUB1LH	←	0	1	0	1	0	1	0	1	Store 55H in address substitution register LH for bank1
ROMSUB1HL	←	0	1	1	0	0	1	1	0	Store 66H in address substitution register HL for bank1.
ROMSUB1HH	←	0	1	1	1	0	1	1	1	Store 77H in address substitution register HH for bank1.

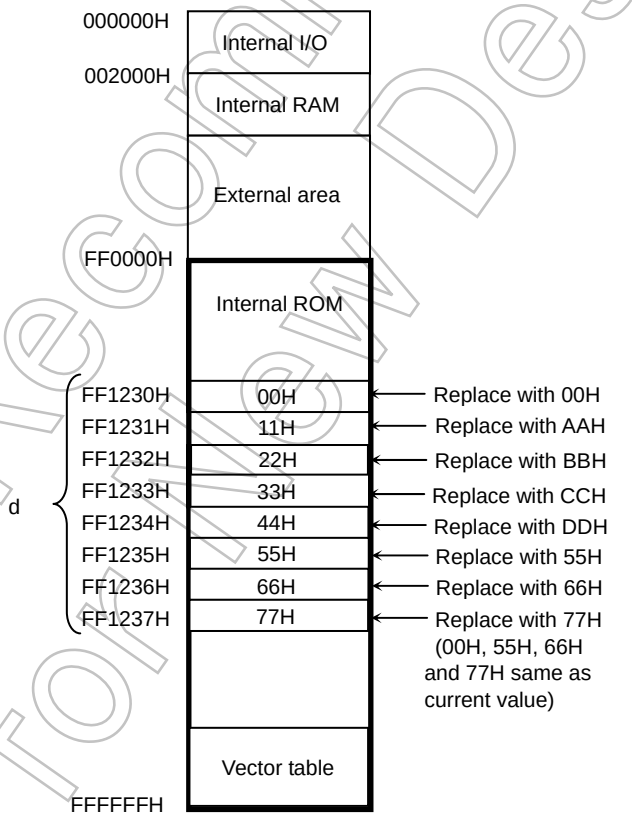

Figure 3.15.21 Example Patch Code Implementation

(2) Using an interrupt to cause a branch

A wider range of program code can also be fixed using a software interrupt (SWI). With a patch code loaded into on-chip RAM, the program patch logic can be used to replace program code at a specified address with a single-byte SWI instruction, which causes a branch to the patch program.

Note that this method can only be used if the original ROM data has been developed with on-chip RAM addresses specified as SWI vector addresses.

Correction procedure:

Load the address compare registers ROMCMPx0 to ROMCMPx2 (x = bank No. 0 to 7) with the start address of the program code that is to be fixed. If it is an even address, store an SWI instruction code (e.g., SWI: F9H) in ROMSUBxLL or ROMSUBxHL. If the start address is an odd address, store an SWI instruction code in ROMSUBxLH or ROMSUBxHH. When the data for the purpose of substitution is required only for 1 to 3 bytes, please set the same data as original ROM data to the remaining data.

When the CPU address matches the value stored in the ROMCMPx0 to ROMCMPx2 registers, the program patch logic disables RD output to the internal ROM and drives out the SWI instruction code to the internal bus. Upon fetching the SWI code, the CPU makes a branch to the internal RAM area to execute the preloaded code.

At the end of the patch program executed from the internal RAM, the CPU directly rewrites the saved PC value so that it points to the address following the patch code, and then executes a RETI.

The following shows an example:

Example: Fixing a program within the range from FF5000H to FF507FH

Before developing the original ROM data, set the SWI1 vector reference address to 002500H (on-chip RAM area).

Use the startup routine to load the patch code to on-chip RAM (002500H to 0025EFH). Store the start address (FF5000H) of the ROM area to be fixed in the ROMCMP00 to ROMCMP02. Store the SWI1 instruction code (F9H) in the ROMSUB0LL and the current data at FF5001H (AAH) in the ROMSUB0LH and the current data at FF5002H (BBH) in the ROMSUB0HL and the current data at FF5003 (CCH) in the ROMSUB0HH. When the CPU address matches the value stored in ROMCMP00 to ROMCMP02, the program patch logic replaces the ROM-based code at FF5000H with F9H. The CPU then executes the SWI1 instruction, which causes a branch to 002500H in the on-chip RAM area. After executing the patch program the CPU finally rewrites the saved PC value to FF5080H and executes a RETI.

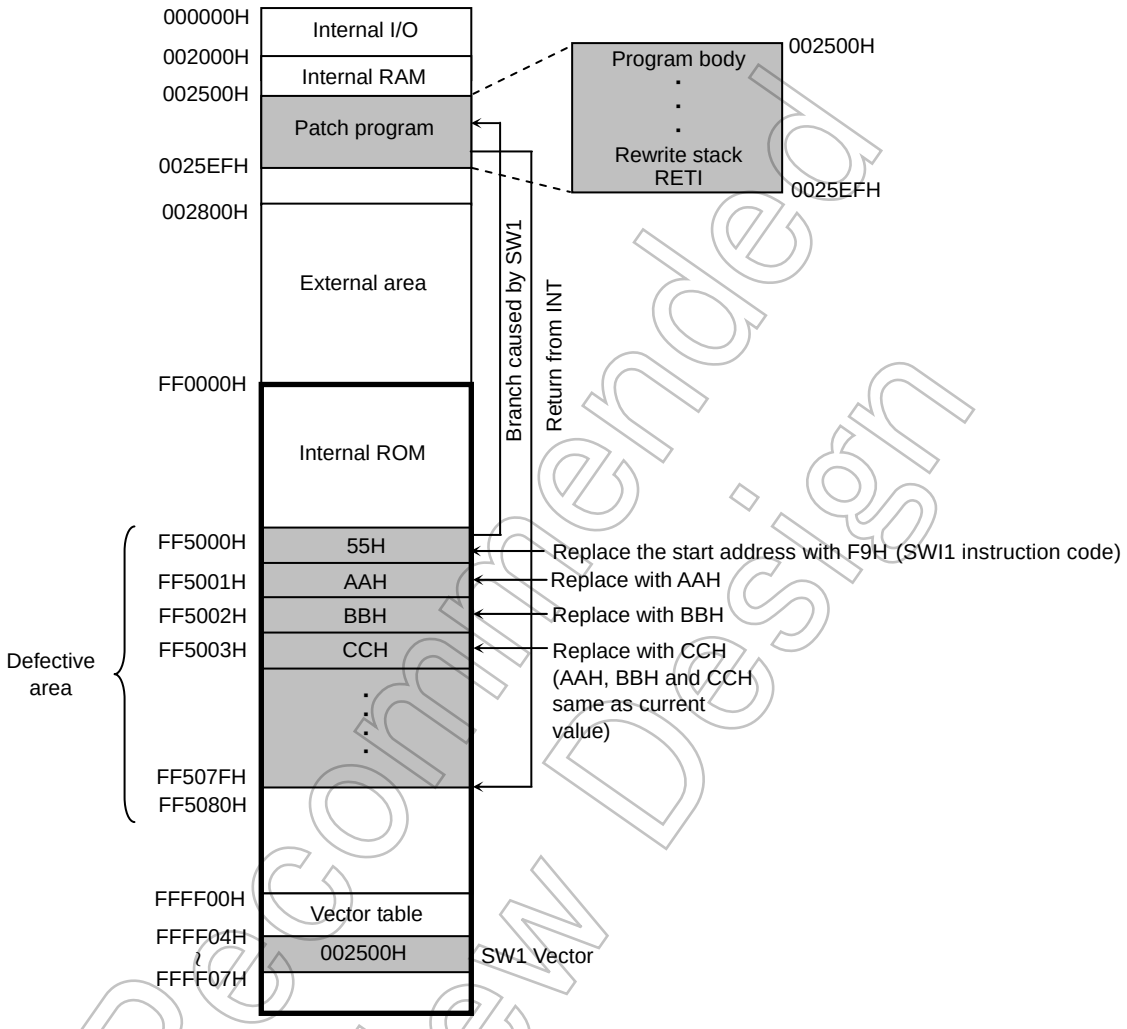

Figure 3.15.22 Example Patch Code Implementation

4. Electrical Characteristics

4.1 Absolute Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	V_{CC}	−0.5 to 4.0	V
Input Voltage	V_{IN}	−0.5 to V_{CC} + 0.5	V
Output Current (1 pin) Except PN1, PN2, PN4 and PN5	I_{OL}	2	mA
Output Current (1 pin) PN1, PN2, PN4 and PN5	I_{OL2}	3.5	mA
Output Current (1 pin)	I_{OH}	−2	mA
Output Current (Total)	ΣI_{OL}	80	mA
Output Current (Total)	ΣI_{OH}	−80	mA
Power Dissipation (Ta = 85°C)	P_D	600	mW
Soldering Temperature (10 s)	T_{SOLDER}	260	°C
Storage Temperature	T_{STG}	−65 to 150	°C
Operation Temperature	T_{OPR}	−40 to 85	°C

Note: The absolute maximum ratings are rated values which must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any absolute maximum rating is exceeded, the device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no absolute maximum rating value will ever be exceeded.

Solderability

Test parameter	Test condition	Note
Solderability	(1) Use of Sn-37Pb solder Bath Solder bath temperature =230°C, Dipping time = 5 seconds The number of times = one, Use of R-type flux	Pass: solderability rate until forming ≥ 95%
	(2) Use of Sn-3.0Ag-0.5Cu solder bath Solder bath temperature =245°C, Dipping time = 5 seconds The number of times = one, Use of R-type flux

15	$\overline{RD}$ High Width	t_{RRH}	0.5T – 15		10	22	ns

Write cycle

V_{CC} = 3.3 ± 0.3V/fc = 6 to 40 MHz/Ta = –40 to 85°C

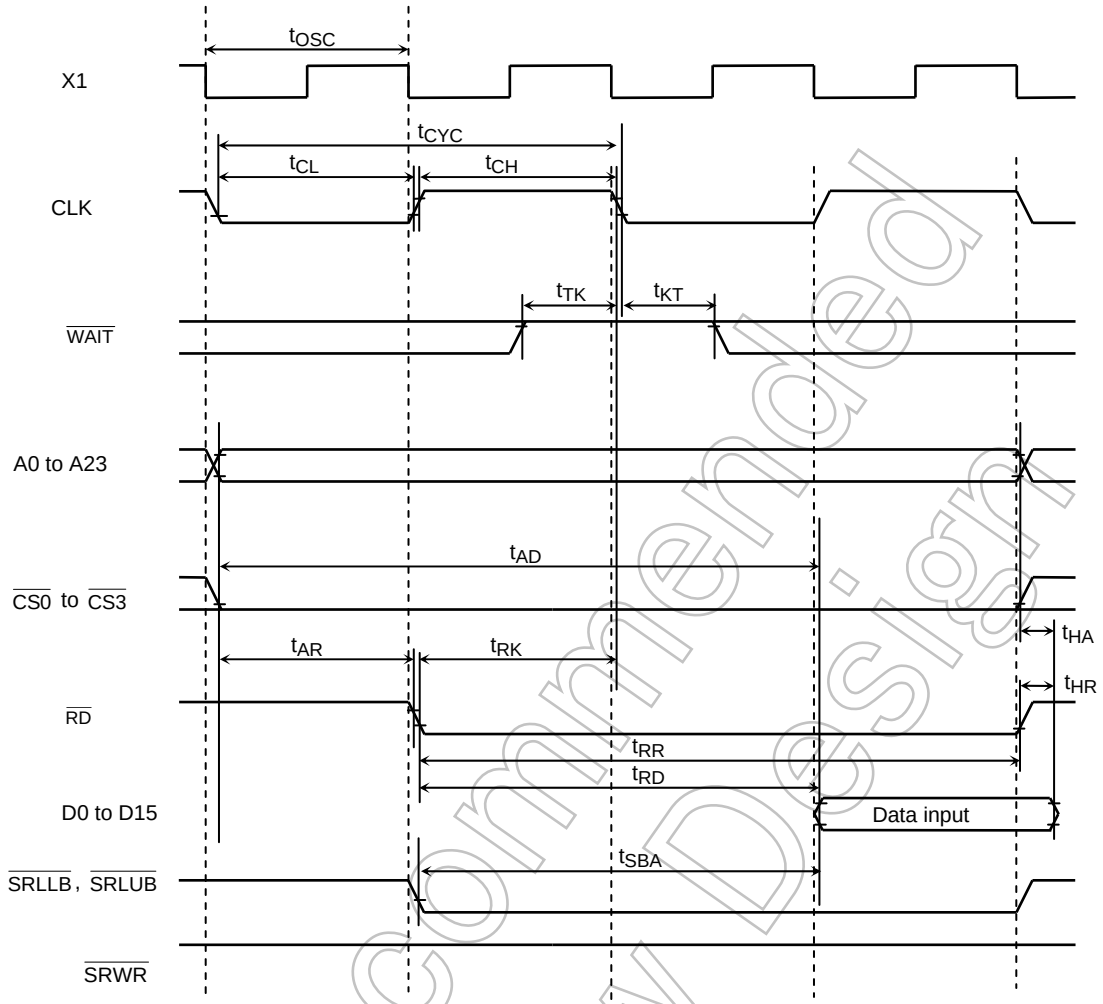
No.	Parameter	Symbol	Variable		f_{SYS} = 20 MHz (fc = 40 MHz)	f_{SYS} = 13.5MHz (fc = 27 MHz)	Unit
			Min	Max			
16	$\overline{SRWR}$ Falling → CLK Falling	t_{SWK}	0.5T – 20		5	17	ns
17	$\overline{SRWR}$ Rising → A0 to A23 Hold	t_{SWA}	0.25T – 5		7.5	13.5	ns
18	$\overline{RD}$ Rising → D0 to D15 Output	t_{RDO}	0.5T – 5		20	32	ns
19	Write Pulse Width for SRAM	t_{SWP}	1.25T – 30		32.5	62.5	ns
20	Data Byte Control to End of Write for SRAM	t_{SBW}	1.25T – 30		32.5	62.5	ns
21	Address Setup Time for SRAM	t_{SAS}	0.5T – 20		5	17	ns
22	Write Recovery Time for SRAM	t_{SWR}	0.25T – 5		7.5	13.5	ns
23	Data Setup Time for SRAM	t_{SDS}	1.25T – 35		27.5	57.5	ns
24	Data Hold Time for SRAM	t_{SDH}	0.25T – 5		7.5	13.5	ns

AC measuring condition

Output: High = 0.7 V_{CC}, Low = 0.3 V_{CC}, C_L = 50 pF

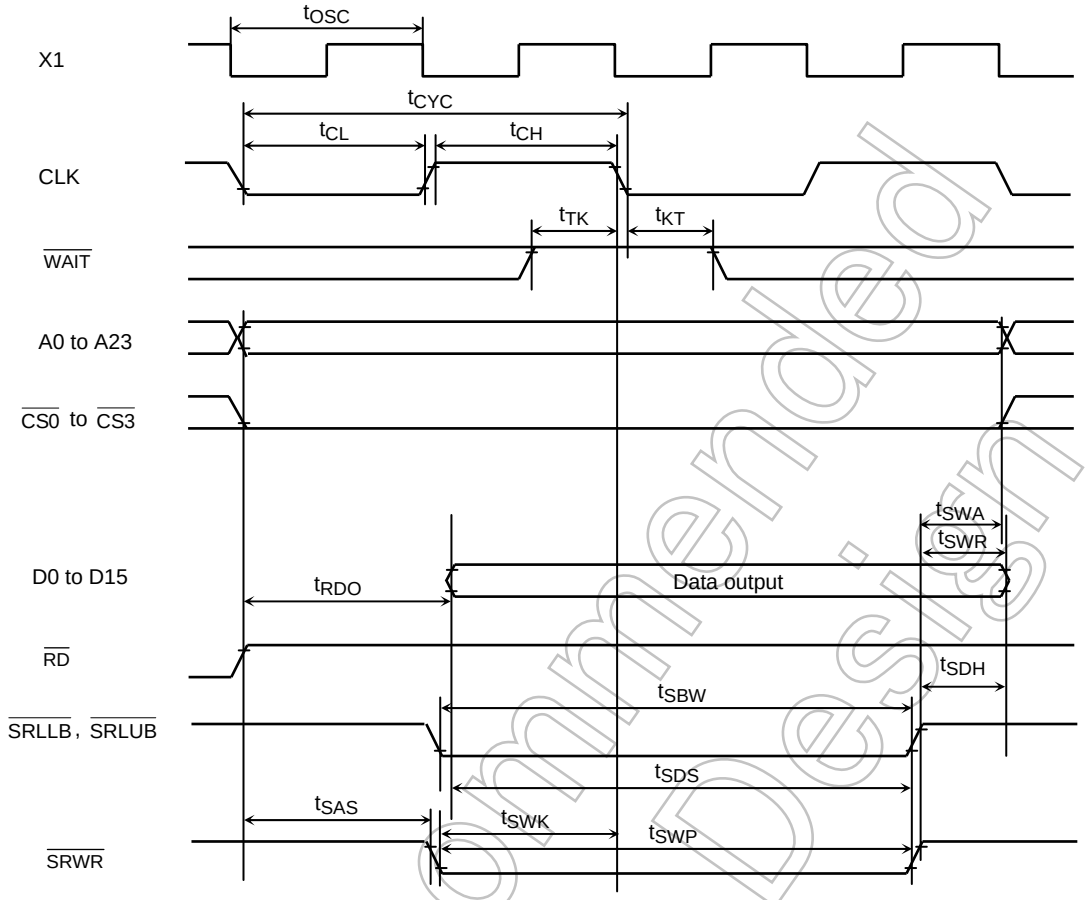
Input: High = 0.9 V_{CC}, Low = 0.1 V_{CC}

(1) Read cycle (0 waits, fc = f_{OSCH}, f_{FPH} = fc/1)



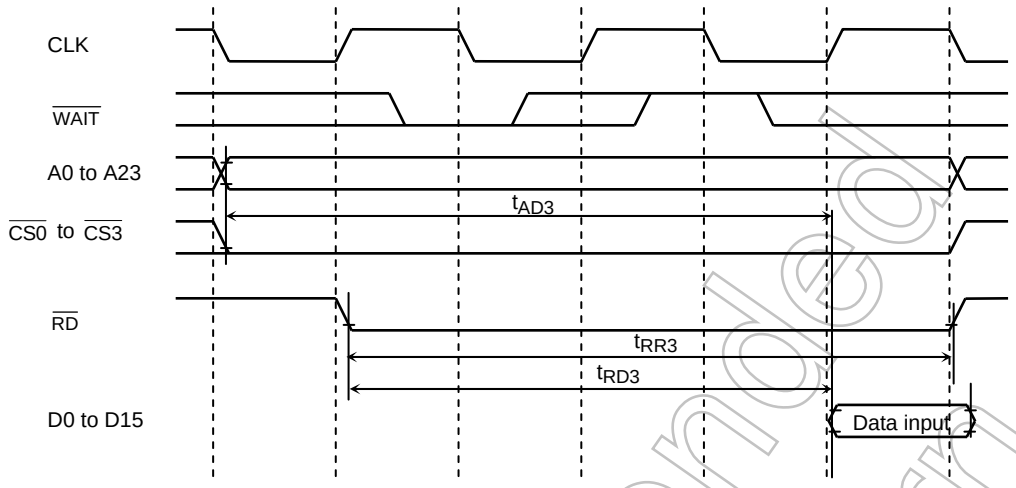
Note: The phase relation between X1 input signal and the other signals is undefined.
The above timing chart is an example.

(2) Write cycle (0 waits, fc = f_{OSCH}, f_{FPH} = fc/1)

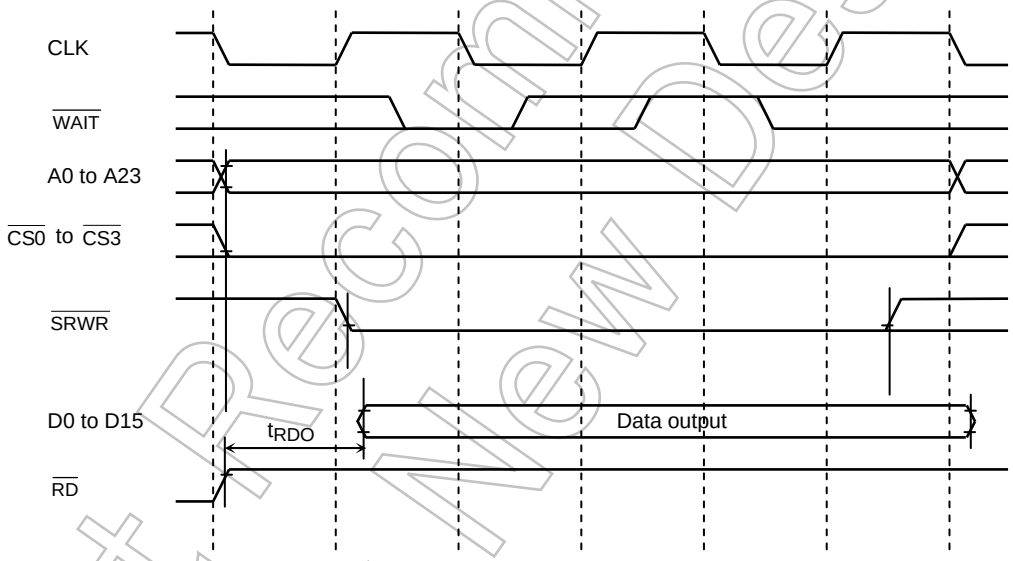


Note: The phase relation between X1 input signal and the other signals is undefined.
The above timing chart is an example.

(3) Read cycle (1 wait, fc = f_{OSCH}, f_{FPH} = fc/1)



(4) Write cycle (1 wait, fc = f_{OSCH}, f_{FPH} = fc/1)



4.3.2 Page ROM Read Cycle

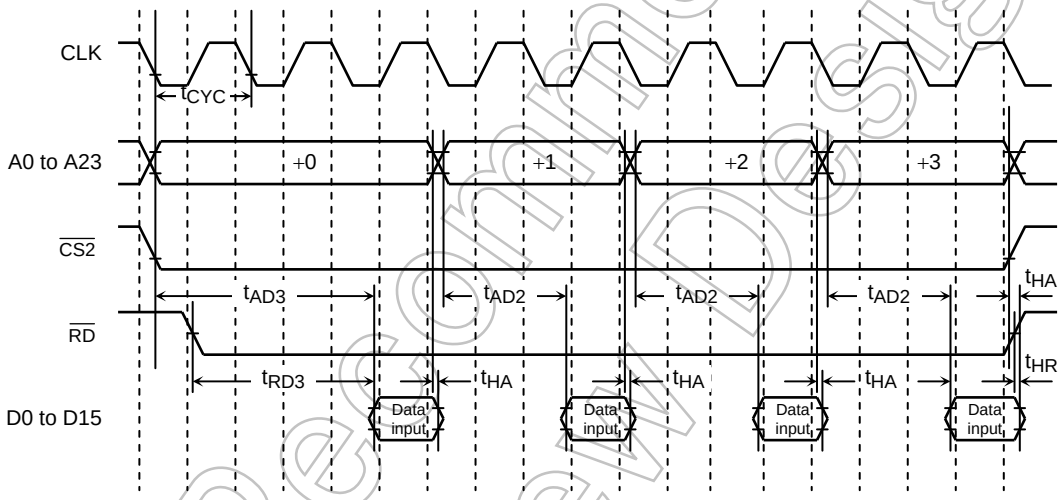
(1) 3-2-2-2 mode

V_{CC} = 3.3 ± 0.3 V/fc = 6 to 40 MHz/Ta = –40 to 85°C

No.	Parameter	Symbol	Variable		f_{SYS} = 20MHz (fc = 40 MHz)	f_{SYS} = 18MHz (fc = 36 MHz)	f_{SYS} = 13.5MHz (fc = 27 MHz)	Unit
			Min	Max				
1	System Clock Period (= T)	t_{CYC}	50		50	55.5	74	ns
2	A0, A1 → D0 to D15 input	t_{AD2}		2.0T – 50	50	61	98	ns
3	A2 to A23 → D0 to D15 input	t_{AD3}		3.0T – 50	100	116.5	172	ns
4	$\overline{RD}$ Falling→ D0 to D15 input	t_{RD3}		2.5T – 45	80	93.8	140	ns
5	A0 to A23 valid → D0 to D15 Hold	t_{HA}	0		0	0	0	ns
6	$\overline{RD}$ Rising → D0 to D15 Hold	t_{HR}	0		0	0	0	ns

AC measuring condition

- Output: High = 0.7 V_{CC}, Low = 0.3 V_{CC}, CL = 50 pF
- Input: High = 0.9 V_{CC}, Low = 0.1 V_{CC}



Timing Pulse Diagram (8-byte setting)

4.3.3 Serial Channel Timing

(1) SCLK input mode (I/O interface mode)

Parameter	Symbol	Variable		f_{SYS} = 20 MHz (fc = 40 MHz)		f_{SYS} = 13.5MHz (fc = 27 MHz)		Unit
		Min	Max	Min	Max	Min	Max	
SCLK cycle	t_{SCY}	16X		0.40		0.59		μs
Output data → SCLK Rising/Falling *	t_{OSS}	$t_{SCY}/2 - 4X - 70$		30		78		ns
SCLK Rising/Falling* → Output Data Hold	t_{OHS}	$t_{SCY}/2 + 2X + 0$		250		370		ns
SCLK Rising/Falling* → Input Data Hold	t_{HSR}	3X + 10		85		121		ns
SCLK Rising/Falling* → Input Data Valid	t_{SRD}		$t_{SCY} - 0$		400		592	ns
Input Data Valid → SCLK Rising/Falling*	t_{RDS}	0		0		0		ns

*: SCLK rinsing/falling edge: The rising edge is used in SCLK rising mode.
The falling edge is used in SCLK falling mode.

Note 1: t_{SCY} = 16X at f_{SYS} = 20MHz or 13.5MHz

Note 2: Symbol x in the above table means the period of clock f_{FPH}, it's half period of the system clock f_{SYS} for CPU core. The period of f_{FPH} depends on the clock gear setting.

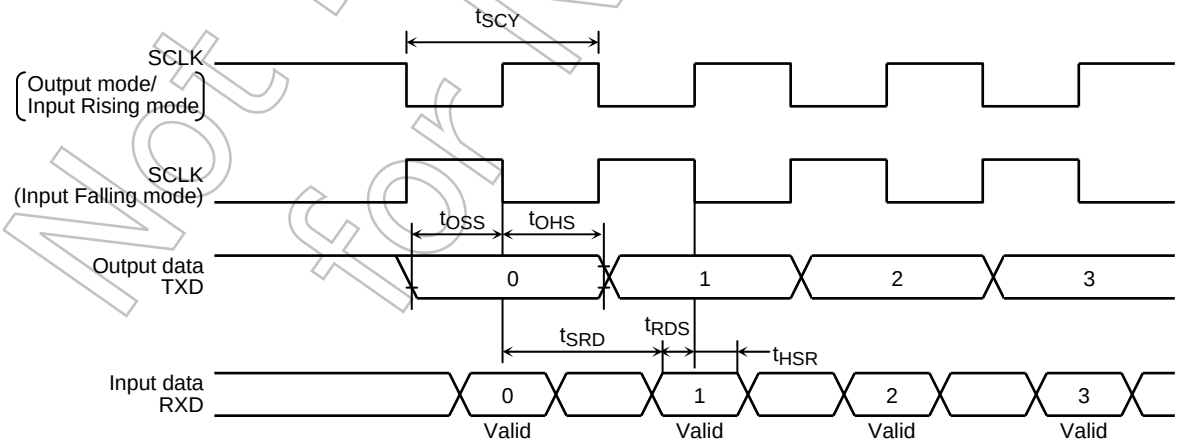
(2) SCLK output mode (I/O Interface mode)

Parameter	Symbol	Variable		f_{SYS} = 20 MHz (fc = 40 MHz)		f_{SYS} = 13.5MHz (fc = 27 MHz)		Unit
		Min	Max	Min	Max	Min	Max	
SCLK cycle	t_{SCY}	16X	8192X	0.40	204	0.59	303	μs
Output data → SCLK Rising/Falling *	t_{OSS}	$t_{SCY}/2 - 40$		160		256		ns
SCLK Rising/Falling* → Output Data Hold	t_{OHS}	$t_{SCY}/2 - 40$		160		256		ns
SCLK Rising/Falling* → Input Data Hold	t_{HSR}	0		0		0		ns
SCLK Rising/Falling* → Input Data Valid	t_{SRD}		$t_{SCY} - 1X - 180$		195		375	ns
Input Data Valid → SCLK Rising/Falling*	t_{RDS}	1X + 180		205		217		ns

*: SCLK rinsing/falling edge: The rising edge is used in SCLK rising mode.
The falling edge is used in SCLK falling mode.

Note 1: t_{SCY} = 16X at f_{SYS} = 20MHz or 13.5MHz

Note 2: Symbol x in the above table means the period of clock f_{FPH}, it's half period of the system clock f_{SYS} for CPU core. The period of f_{FPH} depends on the clock gear setting.



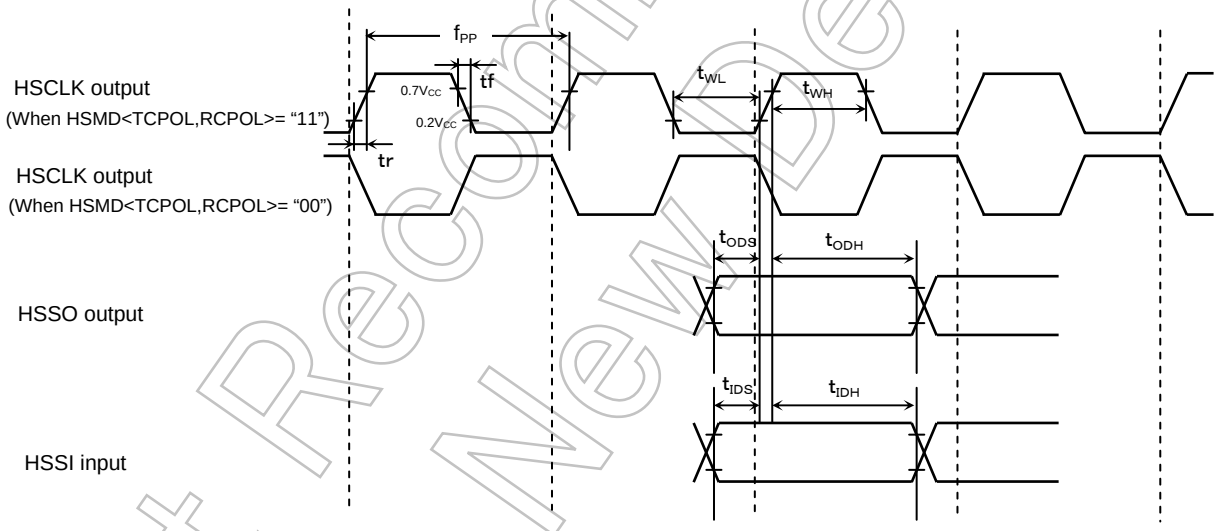
4.3.4 High Speed SIO Timing (High Speed SIO function is not built into TMP92CY23)

Symbol	Parameter	Variable		f_{SYS} = 20MHz (fc = 40 MHz)	f_{SYS} = 18MHz (fc = 36 MHz)	f_{SYS} = 13.5MHz (fc = 27 MHz)	Unit
		Min	Max				
f_{PP}	HSCLK frequency (=1/X)		10	10	9	6.75	MHz
t_r	HSCLK rising timing		8	8	8	8	ns
t_f	HSCLK falling time		8	8	8	8	
t_{WL}	HSCLK Low pulse width	0.5X-8		42	47	66	
t_{WH}	HSCLK High pulse width	0.5X-16		34	39	58	
t_{ODS1}	Output data valid → HSCLK rise	0.5X-18		32	37	56	
t_{ODS2}	Output data valid → HSCLK fall	0.5X-23		27	32	51	
t_{ODH}	HSCLK rise/fall → Output data hold	0.5X-10		40	45	64	
t_{IDS}	Input data valid → HSCLK rise/fall	0X+20		20	20	20	
t_{IDH}	HSCLK rise/fall → Input data hold	0X+5		5	5	5	

AC measuring conditions

Output level : High = 0.7 V_{CC}, Low = 0.2 V_{CC}, C_L = 25 pF

Input level : High = 0.9 V_{CC}, Low = 0.1 V_{CC}



4.3.5 Interrupts

Parameter	Symbol	Variable		f_{SYS} = 20 MHz (fc = 40 MHz)		f_{SYS} = 13.5MHz (fc = 27 MHz)		Unit
		MIN	MAX	MIN	MAX	MIN	MAX	
$\overline{NMI}$, INT0 to INT7 Low level Width	T_{INTAL}	4X + 40		140		188		ns
$\overline{NMI}$, INT0 to INT7 High level Width	T_{INTAH}	4X + 40		140		188		

Note : Symbol x in the above table means the period of clock f_{FPH}, it's half period of the system clock f_{SYS} for CPU core. The period of f_{FPH} depends on the clock gear setting.

4.3.6 Event Counter (TA0IN, TB1IN0, TB1IN1)

Parameter	Symbol	Variable		f_{SYS} = 20 MHz (fc = 40 MHz)		f_{SYS} = 13.5MHz (fc = 27 MHz)		Unit
		MIN	MAX	MIN	MAX	MIN	MAX	
Clock period	T_{VCK}	8X + 100		300		396		ns
Clock Low level Width	T_{VCKL}	4X + 40		140		188		ns
Clock High level Width	T_{VCKH}	4X + 40		140		188		ns

Note : Symbol x in the above table means the period of clock f_{FPH}, it's half period of the system clock f_{SYS} for CPU core. The period of f_{FPH} depends on the clock gear setting.

4.4 AD Conversion Characteristics

Parameter	Symbol	Min	Typ.	Max	Unit
AD Converter Power Supply Voltage	AVCC	VCC	VCC	VCC	V
AD Converter GND	AVSS	VSS	VSS	VSS	
Analog Input Voltage	AVIN	AVSS		AVCC	
Total error (Quantize error of ± 0.5LSB is included)	E_T		±1.0	±4.0	LSB

Note 1: 1LSB = (AVCC − AVSS) / 1024 [V]

Note 2: Minimum frequency for operation

AD converter operatinon is guaranteed only when using fc (high-frequency oscillator). fs is not guaranteed. However, operation is guaranteed if the clock frequency selected by the clock gear is over 4MHz,.

Note 3: The value for I_{CC} includes the current which flows through the AVCC pin.

4.5 Recommended Oscillation Circuit

The TMP92CY23/CD23A has been evaluated by the oscillator vender below. Use this information when selecting external parts.

Note: The total load value of the oscillator is the sum of external loads (C1 and C2) and the floating load of the actual assembled board. There is a possibility of operating error when using C1 and C2 values in the table below. When designing the board, design the minimum length pattern around the oscillator. We also recommend that oscillator evaluation be carried out using the actual board.

(1) Connection example

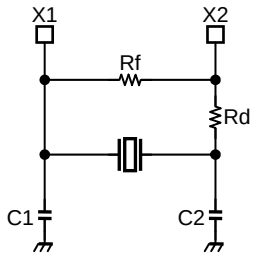


Figure 4.5.1 High-frequency oscillator

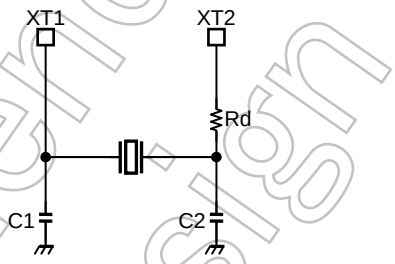

Figure 4.5.2 Low-frequency oscillator

(2) TMP92CY23/CD23A Recommended ceramic oscillator

TMP92CY23/CD23A recommends the high-frequency oscillator by Murata Manufacturing Co., Ltd.

Please refer to the following URL

http://www.murata.com

5. Table of Special function registers (SFRs)

The SFRs include the I/O ports and peripheral control registers allocated to the 8-Kbyte address space from 000000H to 001FFFH.

(1) I/O Port
(2) Interrupt control
(3) DMA controller
(4) Memory controller
(5) Clock control/PLL
(6) 8-bit timer
(7) 16-bit timer
(8) High speed serial channel (Note)
(9) UART/serial channel
(10) I^2CBUS/serial channel
(11) AD converter
(12) Watchdog timer
(13) Special timer for CLOCK
(14) Key-on wake up
(15) Program patch function

Note: High speed serial channel funtion is not built into TMP92CY23.

Table layout

Symbol	Name	Address	7	6			1	0	
									→ Bit symbol
									→ Read/Write
									→ Initial value after reset
									→ Remarks

Note: “Prohibit RMW” in the table means that you cannot use RMW instructions on these registers.

Example: When setting bit0 only of the register PxCR, the instruction “SET 0, (PxCR)” cannot be used. The LD (transfer) instruction must be used to write all eight bits.

Read/Write

R/W:	Both read and write are possible.
R:	Only read is possible.
W:	Only write is possible.
W*:	Both read and write are possible (when this bit is read as1)
Prohibit RMW:	Read-modify-write instructions are prohibited. (The EX, ADD, ADC, BUS, SBC, INC, DEC, AND, OR, XOR, STCF, RES, SET, CHG, TSET, RLC, RRC, RL, RR, SLA, SRA, SLL, SRL, RLD and RRD instruction are read modify write instructions.)
R/W*:	Read-modify-write is prohibited when controlling the pull-up resistor.

			0	0	0	0	0	0	0	0
			0: Port 1: Address bus (A16 to A23)							

Note1: When port P70 to P73 is used in the input mode, P7 register controls the built-in pull-up resistor. Read-modify-write is prohibited in the input mode or the I/O mode. Setting the built-in pull-up resistor may be depended on the states of the input pin.

Note 2: Notes on using low-frequency resonator to P76,P77, it is necessary to set the following procedures to reduce the consumption power supply.

・connecting to a resonator

Set P7CR<P76C,P77C>="11",P7<P76,P77>="00".

・connectiion to an oscillator

Set P7CR<P76C,P77C>="11",P7<P76,P77>="10".

11	SCL1I/O	SDA1 I/O	SCK1 output	SCL0 I/O	SDA0 I/O	SCK0 output

Note 1: When using P83 as a $\overline{WAIT}$ input, while setting it as P8CR<P83C>= "0" and P8FC<P83F> = "1", it is necessary to set memory control register BxCSL<BxWW2:0> or <BxWR2:0> as "011".

Note 2: When setting P80 to P83 as a standard chip select signal ($\overline{CS0}$ to $\overline{CS3}$) output, P8CR is set up after setting up P8FC.

Note 3: PC0 is not based on a functional setup of a port, but is inputted into TA0IN of a 8-bit timer (TMRA0)

Note 4: TB1IN0 and TB1IN1 input is inputted into the 16-bit timer TMRB1 irrespective of a functional setup of a port.

Note 5: RXD2, SCLK2 input, and CTS2 input are inputted into the serial channel 2 irrespective of a functional setup of a port.

Note 6: PD2 does not have a register for 3-state / open drain setup. Moreover, there is no open drain function at the time of an output port.

Note 7: PF0 and PF3 does not have a register for 3-state / open drain setup. Moreover, there is no open drain function at the time of an output port.

Note8: Input channel selection of an AD converter in PG0 to PG7 and PL0 to PL3 is set up by AD mode control register ADMOD1 <ADCH3:0>. Moreover, a setup of AD trigger ($\overline{\text{ADTRG}}$) input permission is set up by ADMOD2 <ADTRGE>.

Note9: Specify the HSCSEL<SIOCNT> when selecting TXD1 or HSSO, RXD1 or HSSI and SCLK1 or HSCLK.

Note10: HSSO, HSSI, HSCLK and <SIOCNT> are not built into TMP92CY23.

6. Port Section Equivalent Circuit Diagram

■ Reading the circuit diagram

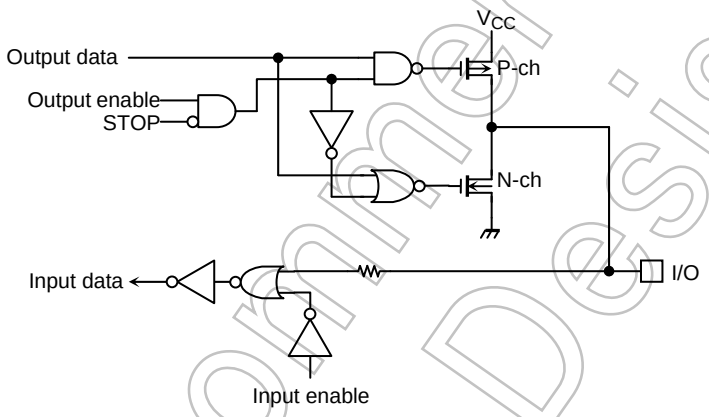
Basically, the gate symbols written are the same as those used for the standard CMOS logic IC [74HCXX] series.

The dedicated signal is described below.

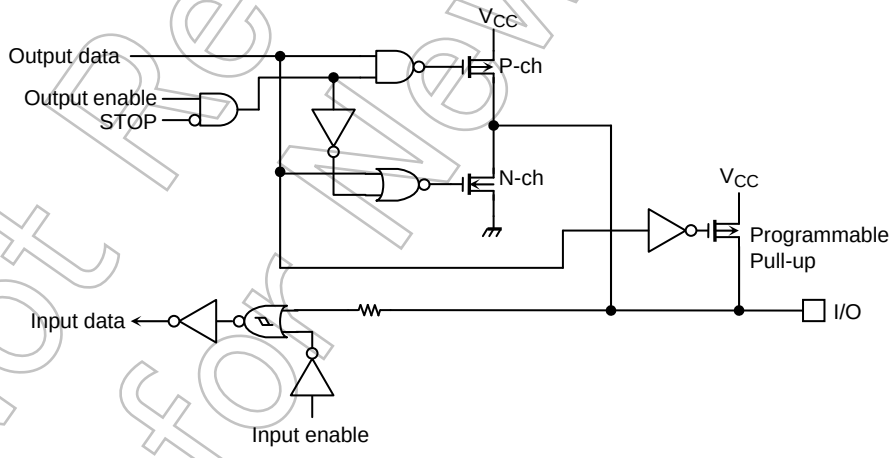
STOP: This signal becomes active “1” when the halt mode setting register is set to the STOP mode and the CPU executes the HALT instruction. When the drive enable bit <DRVE> is set to “1”, however, STOP remains at “0”.

The input protection resistance ranges from several tens of ohms to several hundreds of ohms.

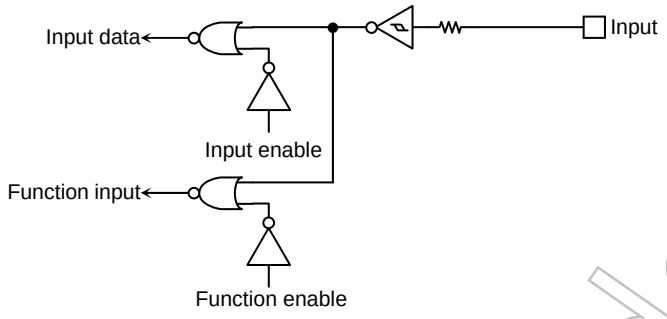
■ P0 (D0 to D7), P1 (D8 to D15), P4 (A0 to A7), P5 (A8 to A15), P6 (A16 to A23)



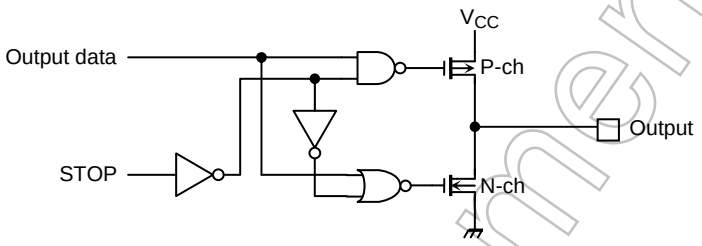
■ P70 ($\overline{RD}$), P71 ($\overline{SRWR}$), P72 ($\overline{SRLLB}$), P73 ($\overline{SRLUB}$)



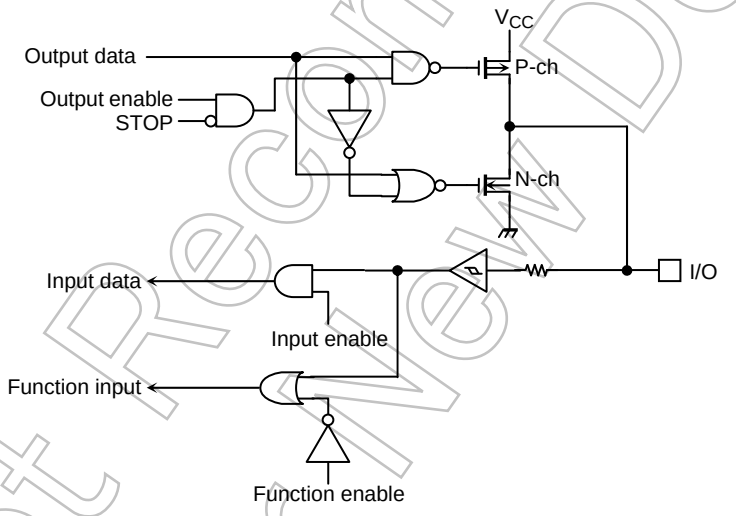
■ P74 (INT0), PC1 to PC3 (INT1 to INT3)



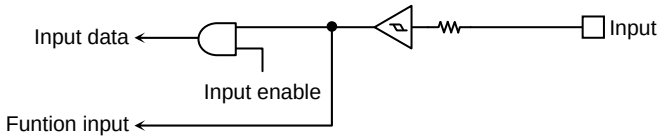
■ P80 ($\overline{CS0}$,TA1OUT), P81 ($\overline{CS1}$,TA3OUT), P82 ($\overline{CS2}$)



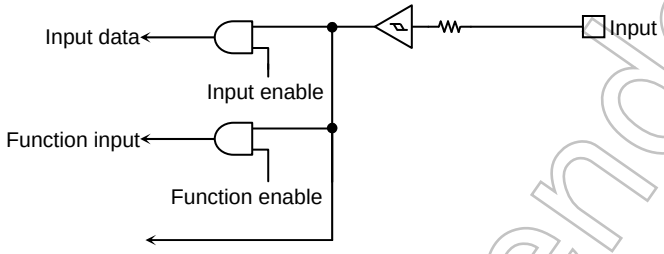
■ P83 ($\overline{CS3}$, $\overline{WAIT}$,TA5OUT), PD0 (INT4,TB0OUT)



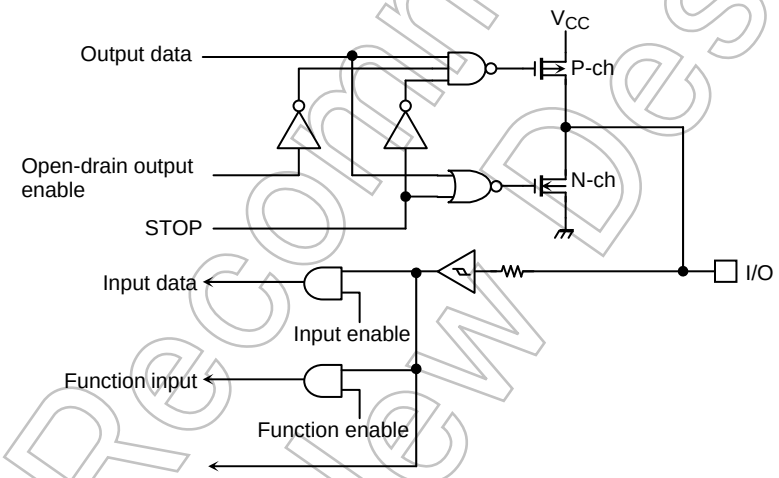
■ PC0 (TA0IN)



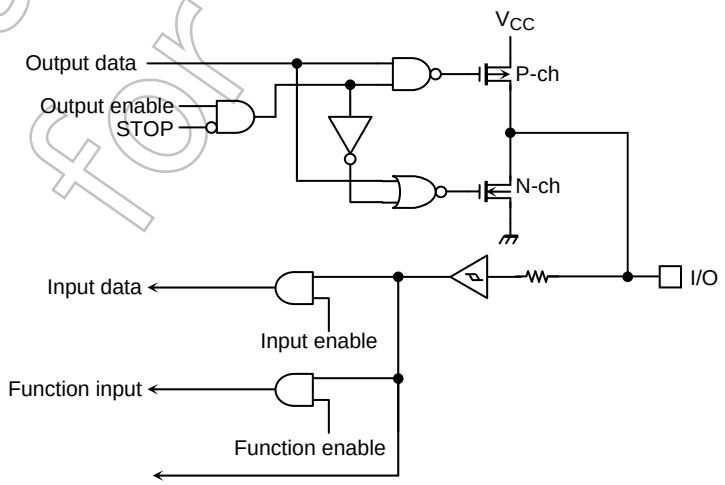
■ PD1 (INT5, TB1IN0), PD3 (INT7, TB1OUT0, RXD2)



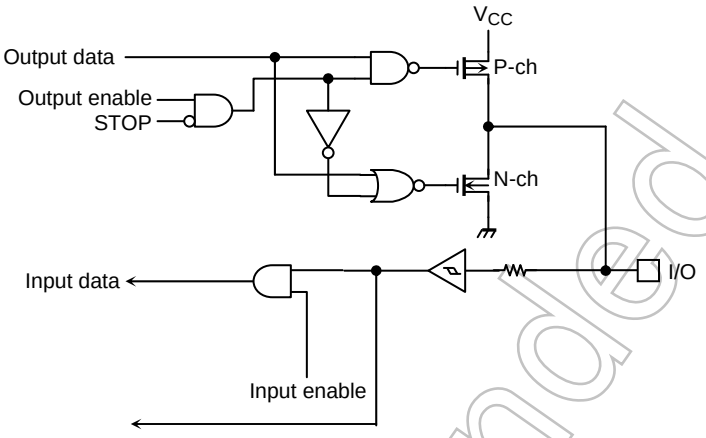
■ PD2 (INT6, TB1IN1, TXD2)



■ PD3 (INT7, TB1OUT0, RXD2)

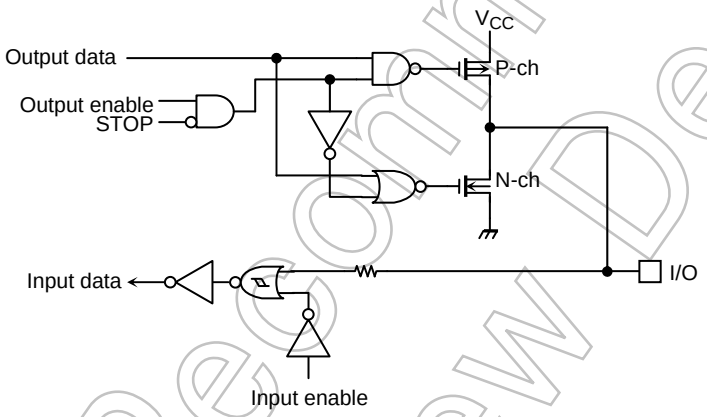


- PD4 (TB1OUT1,SCLK2, $\overline{\text{CTS2}}$), PF1 (RXD0), PF2 (SCLK0, $\overline{\text{CTS0}}$,CLK), PF4 (RXD1, HSSI), PF5 (SCLK1, $\overline{\text{CTS1}}$, HSCLK), PN0 (SCK0), PN3 (SCK1)



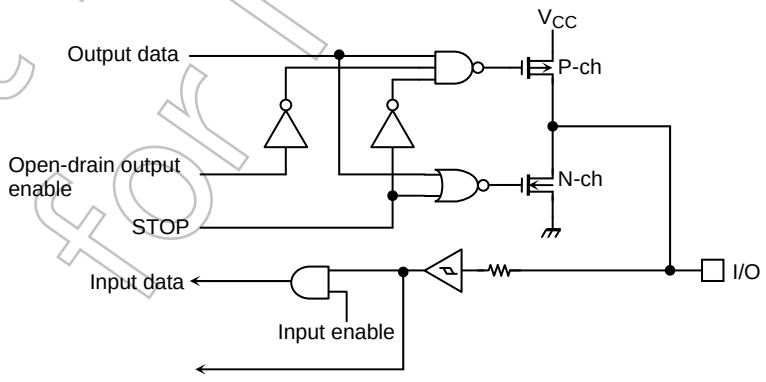
Note: HSSI and HSCLK function are not built into TMP92CY23.

- PF0 (TXD0), PF3 (TXD1, HSSO)

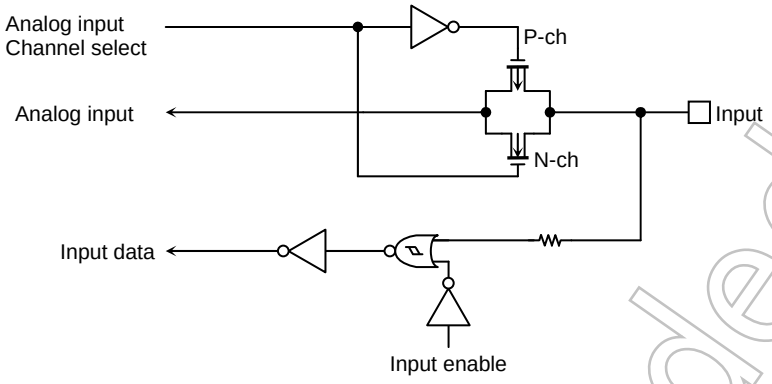


Note: HSSO function is not built into TMP92CY23.

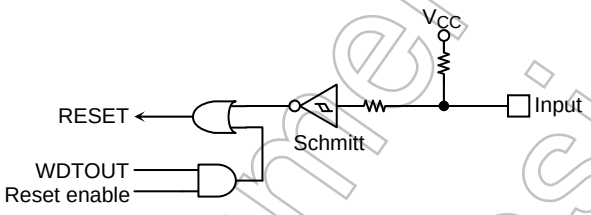
- PN1 (SDA0,SO0), PN2 (SCL0, SI0), PN4 (SDA1, SO1), PN5 (SCL1, SI1)



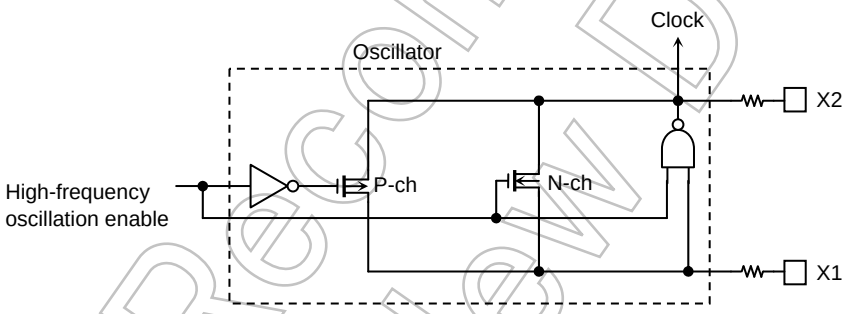
■ PG (AN0 to AN7), PL (AN8 to AN11)



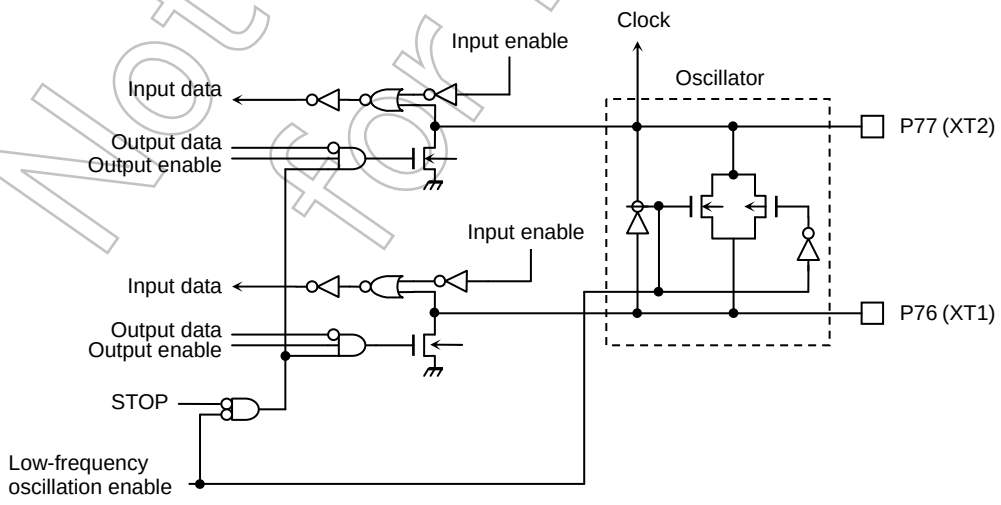
■ $\overline{\text{RESET}}$



■ X1, X2



■ P76 (XT1), P77 (XT2)



■ $\overline{\text{NMI}}$

■ AM0 to AM1

7. Notes and Restrictions

(1) Notation

a. The notation for built-in/ I/O registers is as follows: Register symbol <Bit symbol> (e.g., TA01RUN <TA0RUN> denotes bit TA0RUN of register TA01RUN).

b. Read-modify-write instructions

An instruction in which the CPU reads data from memory and writes the data to the same memory location in one instruction.

Example 1: SET 3, (TA01RUN) ... Set bit 3 of TA01RUN.

Example 2: INC 1, (100H) ... Increment the data at 100H.

- Examples of read-modify-write instructions on the TLCS-900:

Exchange instruction

EX (mem), R

Arithmetic operations

ADD	(mem), R/#	ADC	(mem), R/#
SUB	(mem), R/#	SBC	(mem), R/#
INC	#3, (mem)	DEC	#3, (mem)

Logic operations

AND	(mem), R/#	OR	(mem), R/#
XOR	(mem), R/#		

Bit manipulation operations

STCF	#3/A, (mem)	RES	#3, (mem)
SET	#3, (mem)	CHG	#3, (mem)
TSET	#3, (mem)		

Rotate and shift operations

RLC	(mem)	RRC	(mem)
RL	(mem)	RR	(mem)
SLA	(mem)	SRA	(mem)
SLL	(mem)	SRL	(mem)
RLD	(mem)	RRD	(mem)

c. fc, fs, f_{FPH}, f_{SYS} and one state

The clock frequency input on X1 and 2 is referred to as f_{OSCH}. The clock selected by PLLCR0<FCSEL> is referred to as fc.

The clock selected by SYSCR1<SYSCK> is referred to as f_{FPH}. The clock frequency give by f_{FPH} divided by 2 is referred to as f_{SYS}.

One cycle of f_{SYS} is referred to as one state.

(2) Points to note

a. AM0 and AM1 pins

These pins are connected to the V_{CC} or the V_{SS} pin. Do not alter the level when the pin is active.

b. Reserved address areas

The 16-byte area from FFFFF0H to FFFFFFH is reserved as internal area and cannot be used. When using Toshiba's Flash programming service, prepare your ROM data (Hex file) by leaving these 16 bytes blank or setting them all to "FF" and register it with our ROM data entry system.

Moreover, when using an emulator, since it is used for control of an emulator, 64K bytes with arbitrary 16M byte area of use cannot be performed.

c. HALT mode (IDLE1)

When the HALT instruction is executed in IDLE1 mode (in which only the oscillator operates), the internal Special timer for CLOCK operate. When necessary, stop the circuit by setting RTCCR<RTCRUN> to "0", before the HALT instructions is executed.

d. Warm-up timer

The warm-up timer operates when STOP mode is released, even if the system is using an external oscillator. As a result, a time equivalent to the warm-up time elapses between input of the release request and output of the system clock.

e. Watchdog timer

The watchdog timer starts operation immediately after a reset is released. Disable the watchdog timer when is not to be used.

f. AD converter

The string resistor between the VREFH and VREFL pins can be cut by program so as to reduce power consumption. When STOP mode is used, disable the resistor using the program before the HALT instruction is executed.

g. CPU (Micro DMA)

Only the "LDC cr, r" and "LDC r, cr" instructions can be used to access the control registers in the CPU (e.g., the transfer source address register (DMASn).).

h. Undefined SFR

The value of an undefined bit in an SFR is undefined when read.

i. POP SR instruction

Please execute the POP SR instruction during DI condition.

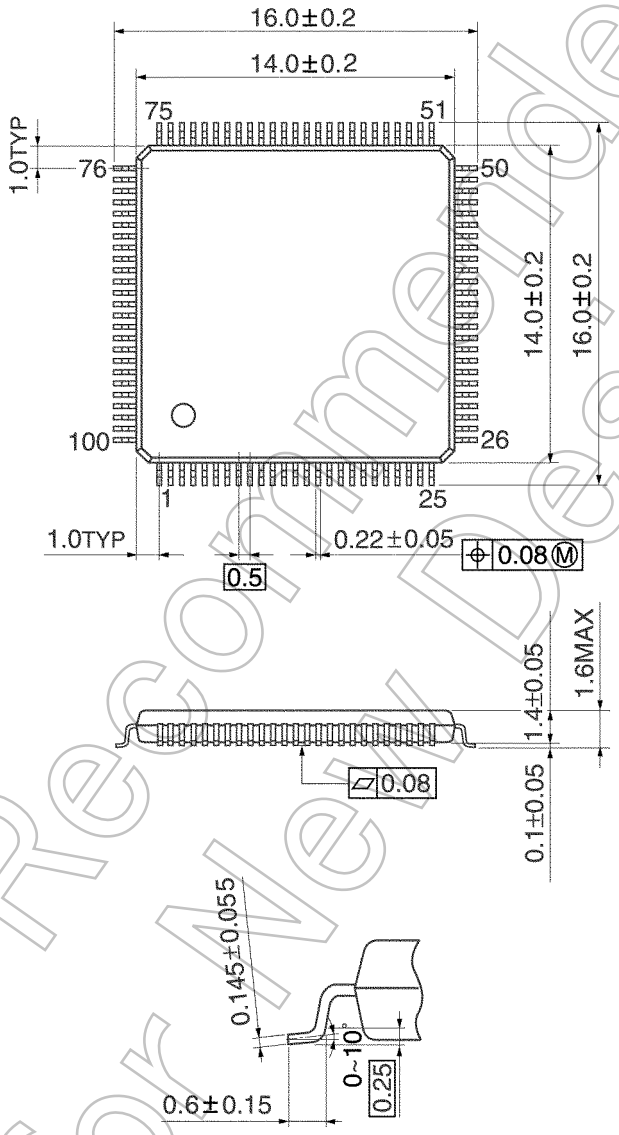
j. Interrupt

When you use interruption, be sure to set "1" as the bit 7 of a SIMC register.

8. Package Dimensions

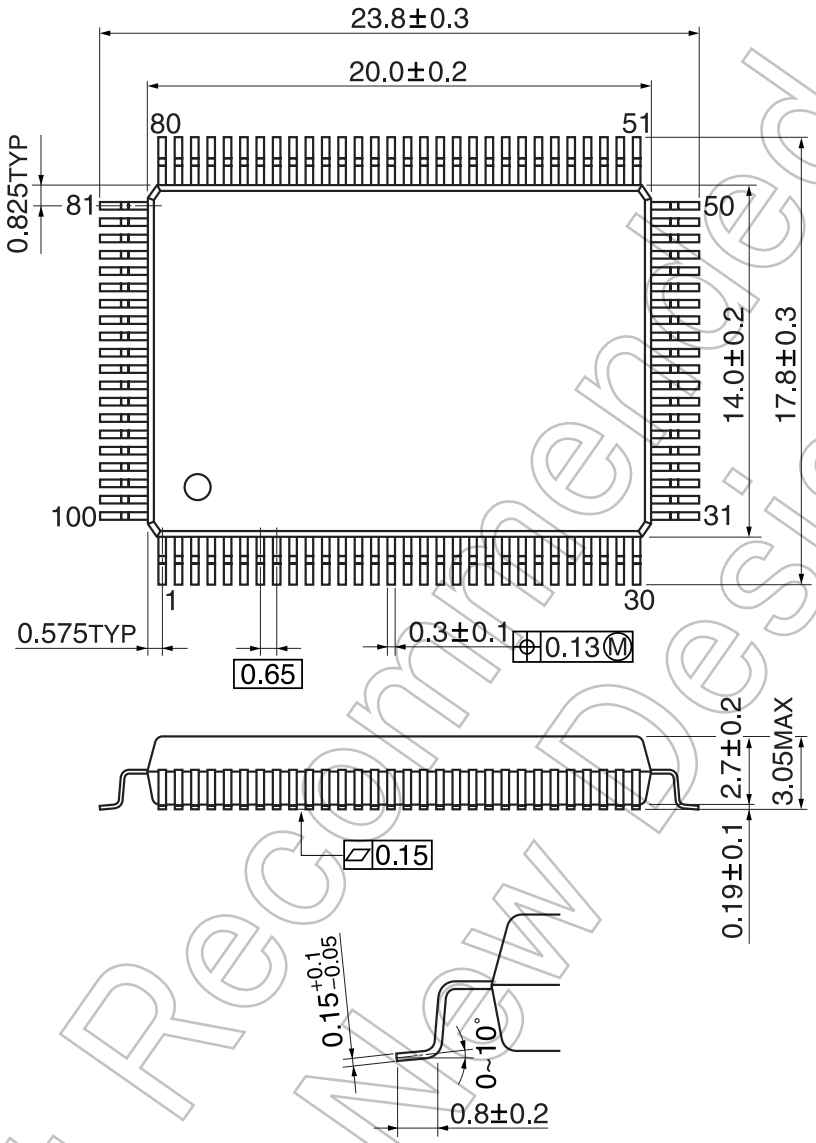
Package Name: LQFP100-P-1414-0.50F

Unit: mm



Package Name: QFP100-P-1420-0.65A

Unit: mm



RESTRICTIONS ON PRODUCT USE

- Toshiba Corporation, and its subsidiaries and affiliates (collectively “TOSHIBA”), reserve the right to make changes to the information in this document, and related hardware, software and systems (collectively “Product”) without notice.
- This document and any information herein may not be reproduced without prior written permission from TOSHIBA. Even with TOSHIBA’s written permission, reproduction is permissible only if reproduction is without alteration/omission.
- Though TOSHIBA works continually to improve Product’s quality and reliability, Product can malfunction or fail. Customers are responsible for complying with safety standards and for providing adequate designs and safeguards for their hardware, software and systems which minimize risk and avoid situations in which a malfunction or failure of Product could cause loss of human life, bodily injury or damage to property, including data loss or corruption. Before creating and producing designs and using, customers must also refer to and comply with (a) the latest versions of all relevant TOSHIBA information, including without limitation, this document, the specifications, the data sheets and application notes for Product and the precautions and conditions set forth in the “TOSHIBA Semiconductor Reliability Handbook” and (b) the instructions for the application that Product will be used with or for. Customers are solely responsible for all aspects of their own product design or applications, including but not limited to (a) determining the appropriateness of the use of this Product in such design or applications; (b) evaluating and determining the applicability of any information contained in this document, or in charts, diagrams, programs, algorithms, sample application circuits, or any other referenced documents; and (c) validating all operating parameters for such designs and applications. **TOSHIBA ASSUMES NO LIABILITY FOR CUSTOMERS’ PRODUCT DESIGN OR APPLICATIONS.**
- Product is intended for use in general electronics applications (e.g., computers, personal equipment, office equipment, measuring equipment, industrial robots and home electronics appliances) or for specific applications as expressly stated in this document. Product is neither intended nor warranted for use in equipment or systems that require extraordinarily high levels of quality and/or reliability and/or a malfunction or failure of which may cause loss of human life, bodily injury, serious property damage or serious public impact (“Unintended Use”). Unintended Use includes, without limitation, equipment used in nuclear facilities, equipment used in the aerospace industry, medical equipment, equipment used for automobiles, trains, ships and other transportation, traffic signaling equipment, equipment used to control combustions or explosions, safety devices, elevators and escalators, devices related to electric power, and equipment used in finance-related fields. Do not use Product for Unintended Use unless specifically permitted in this document.
- Do not disassemble, analyze, reverse-engineer, alter, modify, translate or copy Product, whether in whole or in part.
- Product shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable laws or regulations.
- The information contained herein is presented only as guidance for Product use. No responsibility is assumed by TOSHIBA for any infringement of patents or any other intellectual property rights of third parties that may result from the use of Product. No license to any intellectual property right is granted by this document, whether express or implied, by estoppel or otherwise.
- **ABSENT A WRITTEN SIGNED AGREEMENT, EXCEPT AS PROVIDED IN THE RELEVANT TERMS AND CONDITIONS OF SALE FOR PRODUCT, AND TO THE MAXIMUM EXTENT ALLOWABLE BY LAW, TOSHIBA (1) ASSUMES NO LIABILITY WHATSOEVER, INCLUDING WITHOUT LIMITATION, INDIRECT, CONSEQUENTIAL, SPECIAL, OR INCIDENTAL DAMAGES OR LOSS, INCLUDING WITHOUT LIMITATION, LOSS OF PROFITS, LOSS OF OPPORTUNITIES, BUSINESS INTERRUPTION AND LOSS OF DATA, AND (2) DISCLAIMS ANY AND ALL EXPRESS OR IMPLIED WARRANTIES AND CONDITIONS RELATED TO SALE, USE OF PRODUCT, OR INFORMATION, INCLUDING WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, ACCURACY OF INFORMATION, OR NONINFRINGEMENT.**
- Do not use or otherwise make available Product or related software or technology for any military purposes, including without limitation, for the design, development, use, stockpiling or manufacturing of nuclear, chemical, or biological weapons or missile technology products (mass destruction weapons). Product and related software and technology may be controlled under the Japanese Foreign Exchange and Foreign Trade Law and the U.S. Export Administration Regulations. Export and re-export of Product or related software or technology are strictly prohibited except in compliance with all applicable export laws and regulations.
- Please contact your TOSHIBA sales representative for details as to environmental matters such as the RoHS compatibility of Product. Please use Product in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. TOSHIBA assumes no liability for damages or losses occurring as a result of noncompliance with applicable laws and regulations.
